Mauritania is a North African state bordering the North Atlantic Ocean, between Senegal and Western Sahara. It has a total area of 1 030 700 sq km and it borders with Algeria (463 km), Mali (2237 km), Senegal (813 km), and Western Sahara (1561 km). Mauritania became independent from France in 1960, and despite the legalization of opposition parties through a new constitution approved in 1991, it essentially remains a one-party state.

The total population of 2 998 563 (July 2004 est.) consists of a majority of Arab-Berber ethnic groups (also called Maur or Moors) who continue to experience ethnic tensions with the black minority population.

Hassaniya Arabic, with 2.2 million speakers (66% of the population), acts as the official language, but the Niger-Congo languages Fula (Pulaar) (150 000), Soninke (30 000), and Wolof (10 000) are also spoken and recognized, with Arabic, as official languages

Matsumoto, Katsumi (b. 1929)

Katsumi Matsumoto was born in Nagano, Japan on October 25, 1929. He graduated with a B.A. from the department of linguistics at the University of Tokyo in 1953, and an M.A. from the graduate school there in 1956. He was trained in classical philology and Indo-European comparative linguistics under Harushige Kodzu, late professor of linguistics (*see* **Kodzu, Harushige (1908–1973)**). He was appointed lecturer in linguistics at the University of Kanazawa in 1956, associate professor in 1964, and professor of linguistics in 1975. He studied under W. S. Allen and John Chadwick as a visiting scholar at the University of Cambridge from 1977–1978. He was professor of general linguistics at the University of Tsukuba from 1983 to 1993. Matsumoto was chief editor of *Gengo Kenkyu* from 1983 to 1985 and Japan's representative at the General Assembly of CIPL in 1987. He served as president of the Linguistic Society of Japan from 1991 to 1994.

His major field of study is Indo–European linguistics, especially Ancient Greek, typology, and the genealogical study of Japanese. One of his outstanding and influential contributions to Japanese historical linguistics is his theory on the vowel system of Old Japanese, in which he postulated a 5-vowel system based on internal reconstruction (Matsumoto, 1975b, 1995).

Mauritania is a North African state bordering the North Atlantic Ocean, between Senegal and Western Sahara. It has a total area of 1 030 700 sq km and it borders with Algeria (463 km), Mali (2237 km), Senegal (813 km), and Western Sahara (1561 km). Mauritania became independent from France in 1960, and despite the legalization of opposition parties through a new constitution approved in 1991, it essentially remains a one-party state.

The total population of 2 998 563 (July 2004 est.) consists of a majority of Arab-Berber ethnic groups (also called Maur or Moors) who continue to experience ethnic tensions with the black minority population.

Hassaniya Arabic, with 2.2 million speakers (66% of the population), acts as the official language, but the Niger-Congo languages Fula (Pulaar) (150 000), Soninke (30 000), and Wolof (10 000) are also spoken and recognized, with Arabic, as official languages

that are used in, for example, state radio service broadcasts. Other languages spoken include Bambara and French. Zenaga, a Berber language that is highly endangered, with only a couple of hundred Bedouin speakers recorded in 1998. Fula, Soninke, and Wolof are spoken in the south of the country, on the border with Senegal, where all three languages are spoken as well.

Adult literacy of persons aged 15 and over is 41.7% for the total population, divided into 51.8% males and 31.9% females, based on a 2003 estimate. Youth literacy is by comparison higher at 49.6%.

Linguistic Environment

The Republic of Mauritius contains the islands of Mauritius, Rodrigues, Saint Brandon (itself the name of a group of islands, occasionally referred to as the Cargados Carajos), and Agalega. The people of Saint Brandon and Agalega number only a few hundred, of which many are Mauritians on short-term postings, leaving only Rodrigues and the island of Mauritius as centers of population. The Central Statistical Office of Mauritius estimates the total resident population of the island of Mauritius in mid-2003 to have been 1 186 363 (Central Statistical Office, 2004), with a further 36 448 for Rodrigues. Since the linguistic environments of Rodrigues and the island of Mauritius are quite distinct, the following remarks are restricted to the latter.

With a total land area equivalent to the English county of East Sussex, Mauritius is densely populated; it also represents an extraordinarily multiethnic and multilingual community. Appel and Muysken (1987: 22) succintly summarize the complexity of the Mauritian linguistic situation by pointing out that "over 10 languages have sizable groups of speakers. Most of these are associated with particular ethnic groups, often descendants of migrants from South Asia, and in addition there is the colonial language, French (to some extent sharing this status with English). In between there is Creole [Morisyen], which on the one hand is the ethnic language of a particular group, and on the other hand functions as a lingua franca."

Of all the languages attested in Mauritius, it is the French-based Creole that has attracted the lion's share of linguistic investigation. But if the last three decades have witnessed a steady output of research into Mauritian Creole (Baker, 1972; Chaudenson, 1979; Baker and Corne, 1982; Muysken and Smith, 1986; Adone, 1994), little by comparison has been produced on languages not considered indigenous to Mauritius. This includes the languages that the Mauritian government describes as 'ancestral languages' (ALs), in that they are officially designated as languages spoken by the ancestors of present-day Mauritians at the time of migration to Mauritius. Often, however, such official designation represents political expedience rather than linguistic fact. For example, while Mandarin is the only form of Chinese taught in Mauritian schools, it is not a dialect that would have been spoken by Chinese migrants to Mauritius. The same political fiction notoriously obtains between Hindi and Bhojpuri, the latter having served as a lingua franca for the majority of Mauritians of north Indian origin, and now on the decline, in no small part due to pressure from Hindi, a language perceived as having much higher cultural status (Ramyead, 1985).

The highly competitive nature of the Mauritian labor market means that great emphasis is placed on study and on examination success; the role of languages in the educational system has invariably become a key political issue and one with a strong ethnic dimension. The Constitution of Mauritius (Section 31(2), subsection 3, point 4) divides the population into Hindu, Muslim, and Sino–Mauritian communities, with the catch-all term 'General Population' encompassing the remainder. Many Mauritians from the 'General Population' believe that children of Indian and Chinese origin are unfairly favored by a school system that offers Hindi, Urdu, Marathi, Telugu, Tamil, and Mandarin as optional school subjects (Additional ALs include Urdu and, somewhat disingenuously, Arabic). The removal of ALs from the school syllabus is resisted, in that Mauritians in favour of the teaching of ALs view any such move as indicative of the promotion of the European languages within the educational system and outright demotion of Asian

that are used in, for example, state radio service broadcasts. Other languages spoken include Bambara and French. Zenaga, a Berber language that is highly endangered, with only a couple of hundred Bedouin speakers recorded in 1998. Fula, Soninke, and Wolof are spoken in the south of the country, on the border with Senegal, where all three languages are spoken as well.

Adult literacy of persons aged 15 and over is 41.7% for the total population, divided into 51.8% males and 31.9% females, based on a 2003 estimate. Youth literacy is by comparison higher at 49.6%.

Linguistic Environment

The Republic of Mauritius contains the islands of Mauritius, Rodrigues, Saint Brandon (itself the name of a group of islands, occasionally referred to as the Cargados Carajos), and Agalega. The people of Saint Brandon and Agalega number only a few hundred, of which many are Mauritians on short-term postings, leaving only Rodrigues and the island of Mauritius as centers of population. The Central Statistical Office of Mauritius estimates the total resident population of the island of Mauritius in mid-2003 to have been 1 186 363 (Central Statistical Office, 2004), with a further 36 448 for Rodrigues. Since the linguistic environments of Rodrigues and the island of Mauritius are quite distinct, the following remarks are restricted to the latter.

With a total land area equivalent to the English county of East Sussex, Mauritius is densely populated; it also represents an extraordinarily multiethnic and multilingual community. Appel and Muysken (1987: 22) succintly summarize the complexity of the Mauritian linguistic situation by pointing out that "over 10 languages have sizable groups of speakers. Most of these are associated with particular ethnic groups, often descendants of migrants from South Asia, and in addition there is the colonial language, French (to some extent sharing this status with English). In between there is Creole [Morisyen], which on the one hand is the ethnic language of a particular group, and on the other hand functions as a lingua franca."

Of all the languages attested in Mauritius, it is the French-based Creole that has attracted the lion's share of linguistic investigation. But if the last three decades have witnessed a steady output of research into Mauritian Creole (Baker, 1972; Chaudenson, 1979; Baker and Corne, 1982; Muysken and Smith, 1986; Adone, 1994), little by comparison has been produced on languages not considered indigenous to Mauritius. This includes the languages that the Mauritian government describes as 'ancestral languages' (ALs), in that they are officially designated as languages spoken by the ancestors of present-day Mauritians at the time of migration to Mauritius. Often, however, such official designation represents political expedience rather than linguistic fact. For example, while Mandarin is the only form of Chinese taught in Mauritian schools, it is not a dialect that would have been spoken by Chinese migrants to Mauritius. The same political fiction notoriously obtains between Hindi and Bhojpuri, the latter having served as a lingua franca for the majority of Mauritians of north Indian origin, and now on the decline, in no small part due to pressure from Hindi, a language perceived as having much higher cultural status (Ramyead, 1985).

The highly competitive nature of the Mauritian labor market means that great emphasis is placed on study and on examination success; the role of languages in the educational system has invariably become a key political issue and one with a strong ethnic dimension. The Constitution of Mauritius (Section 31(2), subsection 3, point 4) divides the population into Hindu, Muslim, and Sino–Mauritian communities, with the catch-all term 'General Population' encompassing the remainder. Many Mauritians from the 'General Population' believe that children of Indian and Chinese origin are unfairly favored by a school system that offers Hindi, Urdu, Marathi, Telugu, Tamil, and Mandarin as optional school subjects (Additional ALs include Urdu and, somewhat disingenuously, Arabic). The removal of ALs from the school syllabus is resisted, in that Mauritians in favour of the teaching of ALs view any such move as indicative of the promotion of the European languages within the educational system and outright demotion of Asian

languages. Given the existence of an economically powerful Franco–Mauritian community with which the use of French is principally associated, any move to reduce the role of the ALs in schools would invariably be seen as socioeconomically and ethnically motivated as well as socioculturally oppressive.

Current Languages

English is the *de facto* official language of Mauritius; it is not constitutionally enshrined as such. The use of French has been maintained by Franco–Mauritians and cultivated by Mauritians from traditionally non-Francophone backgrounds, to the point where it is an 'unofficial official language' alongside English. That is not to say that the domains of use for the two languages are identical: With French as with the ALs, an association exists between language, culture, and ethnicity. Baker (1972) refers to a historical resentment between Franco–Mauritian and Indo–Mauritian communities, in which the use French became emblematic of Franco–Mauritian socioeconomic and political paramountcy. The use of French rather than the more egalitarian lingua franca, Creole, tends still to be restricted to particular aspects of commerce, such as the banking sector and shops selling luxury goods, or when engaging in high culture. English, on the other hand, is strongly associated with business, technology, government, and administration, and not with a particular ethnic community; unlike French, its use in cultural activities would appear to be negligible (Biltoo, 2004).

Data presented by Sambasiva Rao and Sharma (1989) indicate 22 languages as currently spoken in Mauritius but, in adhering closely to census data and including extraterritorial languages returned by a few dozen Mauritian respondents (such as Russian and Italian), this somewhat overstates the multilingual situation. A more realistic enumeration is to be found in Stein (1982), who lists 13 languages. Importantly, Stein does not distinguish individual varieties of Chinese, includes Kutchi and Sindhi, and makes no mention of Arabic. On the basis that Mauritian censuses have in the past returned a number in excess of 1000 for both Hakka [Chinese, Hakka] and – more problematically – 'Chinese,' a more balanced approach would be to separate 'Chinese' into Hakka and Mandarin, disregarding Cantonese. It is doubtful whether Cantonese, Kutchi and Sindhi should be counted as current languages, given the small numbers of speakers indicated in census reports; as for Arabic, it is clear that this is a language reserved for religious practice rather than everyday communication. The list of current languages, even with the excisions suggested above, is nevertheless impressive for a nation with the population and land mass of Mauritius: Bhojpuri, Creole, English, French, Gujarati, Hakka, Hindi, Mandarin, Marathi, Tamil, Telugu, and Urdu.

Maxims and Flouting

A K Greenall, Norwegian University of Science and Technology, Trondheim, Norway

© 2006 Elsevier Ltd. All rights reserved.

Maxims and *flouting* are two closely interrelated terms central to the Oxford language philosopher H. Paul Grice's famous theory of the Cooperative Principle, which first emerged in the William James lectures that Grice delivered at Harvard University in 1967 (*see* **Cooperative Principle; Grice, Herbert Paul (1913–1988)**.) Grice's project was to try to reduce the number of meanings for lexical items ("Grice's razor" [Davis, 1998: 20]), and he did this by postulating a new, separate type of non-semantic meaning that he called *implicature*, a type of meaning that is not semantically coded but arises in conversational context (*see* **Implicature**).

The generation of implicature is crucially connected to the workings of an overall *Cooperative Principle* and a set of conversational *maxims*.

The Cooperative Principle

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged (Grice, 1989).

The Maxims

Quantity

1. Make your contribution as informative as is required.
2. Do not make your contribution more informative than is required.

Quality

1. Do not say what you believe to be false.
2. Do not say that for which you lack adequate evidence.

Relation

1. Be relevant.

Manner

1. Avoid obscurity of expression.
2. Avoid ambiguity.
3. Be brief.
4. Be orderly.

These maxims may either be observed or breached, and in both cases implicatures may arise. The maxims can be contravened in a number of different ways, but crucial importance was allotted to the *blatant*, *intentional* contravention of one (or more of the) maxim(s), or *flouting*. On spotting such a blatant breach, the hearer – who will always retain his or her belief that the speaker is being cooperative – will immediately begin a search for an additional or alternative meaning for the utterance, one that *observes* the maxim(s) in question and thus follows the Cooperative Principle. The result of such a search is the implicature. Consider the following example:

A: Are you going to Anna's party?
B: Well, Anna's got this new boyfriend now.

B's reply here clearly breaches Grice's maxim of Relation (the only truly relevant answers to A's question would be *yes* or *no*). According to the theory, spotting this breach would set off a reasoning process in A, along the following lines:

1. B has said that *Anna's got this new boyfriend now.*
2. This utterance breaches the maxim of Relation.
3. I have, nevertheless, no reason to believe that B does not intend to observe the Cooperative Principle and the maxims.
4. B could not be doing this unless what he really wanted to convey was something different from what he literally says.
5. On the basis of the available context (e.g., that B really liked Anna's old boyfriend), what B really wanted to convey was, *no* (*I am not going to Anna's party*) (a *relevant* reply, i.e., one that is not in breach of the maxim of Relation).

Note how this example illustrates the context-dependency of implicatures. If the context assumed in 5 were *B really* disliked *Anna's old boyfriend*, the interpretation (implicature) would be the opposite, namely, *yes* (*I am going to Anna's party*). (*see* **Context, Communicative**.)

What Is a Maxim?

The concept of maxim is a crucial notion within the theory of the Cooperative Principle. Grice's own characterization of the entity is many-faceted. First of all, he was unambiguous on the point that the maxims are descriptive rather than prescriptive. Our rational nature, according to Grice, leads to the observable situation that the maxims are observed (more often than not). That is, he never meant that the maxims *should always* be observed, one of several common

misunderstandings which has marred the field of Gricean pragmatics since its beginning (Thomas, 1995: 56).

Another noteworthy aspect of Grice's characterization of his maxims is that just because they are seen to have a basis in human rationality, they are not therefore to be considered innate. Furthermore, he was also attracted to the idea of maxims as *general interactional principles* governing both non-verbal and verbal behavior. Finally, the proposed set of maxims was seen as *expandable*: "There are, of course, all sorts of other maxims (aesthetic, social, or moral in character), such as 'Be polite,' that are also normally observed by participants in talk exchanges, and these may also generate . . . implicatures" (Grice, 1989: 28).

In the post-Gricean literature, there are roughly three main approaches to maxims. The first tries to tighten the association between the maxims and human rationality. The main representative of this approach, Asa Kasher, does this by postulating principles of rationality from which Grice's maxims are seen to derive (Kasher, 1976). The second, more influential approach, alienates itself most strongly from Grice's original formulation: here, the maxims are redefined as innate, linguistic rules that are always observed and that will produce the same implicatures irrespective of context (e.g., Atlas and Levinson, 1981; Horn, 1984). This formalist, cognitivist approach, in its quest to 'purge' the Gricean scheme, often ends up reducing the number of proposed maxims, a trend that culminated in the theory of relevance proposed by Sperber and Wilson in 1986, in which all the maxims were collapsed into one, cognitive, Principle of Relevance. This is in stark contrast to a completely opposite trend, found in the third approach to maxims, the social pragmatics approach. Geoffrey Leech (1983), adopting Grice's view of maxims as learned entities, ends up adding a large number of maxims to Grice's scheme.

The main drawback of the formalist, cognitivist approach is clear: they see maxims as rules that are in principle always followed, and hence this kind of theory cannot account for that which is observed when some such entity as a maxim is *breached* (e.g., flouted), namely, the emergence of a layer of underlying meaning (implicature). Support for this observation has come from a perhaps unusual angle: research in Artificial Intelligence has shown that, in order for computers to communicate efficiently with human beings, they need to observe all the Gricean maxims at all times. If they do not, the human communicator will invariably read more into the computer's utterance than the devisers of the program intended (Bernsen *et al.,* 1996).

The main criticism of the social pragmatic approach has revolved around their uncritical, *ad hoc* proliferation of maxims (see, e.g., Brown and Levinson, 1987). A weakness of *all* approaches, including the social pragmatics approach, is the widespread belief that there must be an ultimate, fixed set of universal maxims where each can be classified and labeled individually. This despite the fact that the universality of maxims was drawn strongly into question as early as the mid-1970s, in Elinor Keenan's (1976) famous study of a Malagasy community, in which the influence of an informativity maxim (Quantity) was shown to be absent in certain speech situations. Unfortunately, rather than drawing attention to the eclectic sociocultural reality of Gricean maxims and other such entities, Keenan's work was applauded as a refutation of Grice's claims by those who believe that universality is the only valid stamp of approval for maxims.

The varied appearance of maxims around the world makes likely the hypothesis that one cannot ever hope to be able to enumerate and label every single maxim – the list of entities that can be flouted to produce implicature is probably open-ended. This, of course, calls for a detailed and succinct definition of the notion, to stand guard at the door, controlling which new maxims get in. A simple solution would be to adopt a functional definition such as that proposed by François Recanati (1987: 133), to the effect that a maxim is an entity that can be flouted to produce implicature (see also Levinson's 'general principle' [1983: 132]). The success of such a definition would, however, depend on whether or not one has reached a satisfactory understanding of the notion of *flouting*.

Flouting: Past, Present, and Future

As was noted in the first section of this article, flouting is the blatant breach of one of the maxims. Because all hearers embody faith in the speaker's inherent intention to be cooperative (i.e., to observe the maxims [at some level]), a seeming breach will trigger a reasoning process whereby the hearer will try to come up with a meaning for the utterance that *turns it into* an act of observing the given maxim(s) (an implicature).

There are several problems with this model. First of all, it is unlikely that it is the hearer's belief in the speaker's cooperativity that is the reason behind the former's quest to retrieve an implicature. This is especially the case if one chooses to include politeness maxims into the scheme: if a politeness maxim is breached, the implicature is hardly ever more polite than the act itself (consider, e.g., the act of turning

away when one should have greeted somebody, in order to implicate, for instance, that one considers that person to have done something despicable). Another serious problem is that the reasoning process the hearer is supposed to go through is psychologically implausible. And finally, the end product of this process, the implicature, is presented as an entity that is easily circumscribed (a fully fledged proposition), whereas real life might prove to be far less ordered, with several half-formed, semi-verbalized hypotheses as outcome.

Despite these problems, which are clearly in need of serious attention, there has been a curious neglect of the notion of flouting in post-Gricean theory-building. The interest from empirical researchers has, by contrast, been tremendous. The notion is used as an analytical tool in a large array of studies in a multitude of extra-pragmatic and semi-pragmatic fields such as, e.g., literary criticism (e.g., Bollobás, 1981), humor studies (e.g., Attardo, 1990), or gender studies (Rundquist, 1992). Such widespread application clearly confirms the theoretical value of the notion. However, as very few have felt the need to make any significant amendments to the theory (apart from the occasional addition of a 'new maxim'), the problems remain.

In the theoretical literature, it is mainly the strong focus on observance (largely because of a reluctance to deal with the troublesome notion of context) that has obscured the need to deal with the notion of flouting. The discussion above related the formalist approach with their definition of maxims as context-independent rules that are always to be observed. Another trend manifests itself by interpreting every observed breach of a maxim not as a breach, but as the observance of an invented, 'opposite' maxim (e.g., a breach of Be brief would be seen as an observation of 'Be wordy') (see, e.g., Joshi, 1982).

A particularly serious form of neglect is, of course, outright rejection, as in Sperber and Wilson's highly influential, and heavily criticized, Relevance Theory (1995). (*see* **Relevance Theory**.) Maxims, as envisaged by Grice, are afforded no place in a theory of indirectness, and the notion of flouting leading to implicature is replaced by the idea that implicature should be arrived at by a continued search for relevance, when the literal interpretation yields none. The problem for Relevance Theory is, of course, empirical evidence such as that mentioned in the previous section (Bernsen *et al.,* 1996), which shows without a shadow of a doubt that maxims (or something like them) *are* involved and that breaching them *does* have the effect of stimulating the interpretation of indirect meaning. In addition, there are interesting indications that Grice may have stumbled on to something that is in reality part of an even larger scheme than he envisaged. In experimental social psychology, it has long been noted that 'unusual events' are sociocognitive triggers for a search for an 'explanation' (the 'expectancy principle' [Weiner, 1985: 81]). The breach of a maxim, being the departure from a norm, is also in this sense an 'unusual event,' and the search for an implicature has much in common with the description of the search for an 'explanation.' If this connection is viable, it holds great promise for the further development of Grice's model of flouting.

Conclusion

All in all, Grice himself offered merely 20 or so pages on the topic of maxims and flouting. Subsequent research offers much food for thought, but no viable theory has emerged that exploits the full potential of Grice's eminent point of departure. This does not mean that it is an impossible task to arrive at such a theory, but it would probably require a considerable reorientation of focus, possibly toward the sociocultural significance of both maxims and flouting.

Mayenowa, Maria Renata (1910–1988)

R A Rothstein, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Maria Renata Mayenowa (née Gurewicz) was born on June 2, 1910, in Belostok, Russia (from 1919 Białystok, Poland) and died on May 7, 1988, in Warsaw. She studied Polish language and literature at Stefan Batory University in Wilno, graduating in 1932. After teaching for four years in a Jewish high school she returned to the university, earning her doctorate in May 1939. She worked as a teaching assistant at the university (after 1939 the Vilnius University in Soviet Lithuania) until the Nazi invasion of 1941. She survived the occupation in hiding in northern Lithuania.

After working as a librarian in the Białystok City Library in 1945, she spent the next five years in Prague, where her husband, Józef Mayen, was press-attaché at the Polish Embassy. In 1948 she was one of the cofounders of the Institute for Literary Studies of the Polish Academy of Sciences (IBL PAN); she served as deputy director of IBL from 1957 to 1968. She held the rank of professor at the academy and at Warsaw University from 1954 until 1968, when she was dismissed as a result of the 'anti-Zionist' campaign of that year. She remained active, however, as a scholar, editor, and organizer of scholarly activity to her very last days.

The main focus of Mayenowa's individual publications was a linguistically informed stylistics and poetics, summed up in her 1974 handbook *Theoretical Poetics: Questions of Language* (in Polish; second, enlarged and revised edition 1979), which she characterized as dealing with the question of "what in verbal messages (especially those belonging to literature) is determined by their linguistic character." (p. 5) Stylistics and poetics were also at the center of her work as editor and translator, which resulted in collective volumes with titles like *Tekst, język, poetyka* (Text, language, poetics); *Semantyka tekstu i języka* (The semantics of text and language); *Tekst i język: problemy semantyczne* (Text and language: semantic problems); *O spójności tekstu* (On textual coherence), as well as annotated collections of translations of French, Czech, and Russian works on stylistics. Several of the volumes were the result of the symposia that she organized in Warsaw; they brought together linguists and literary scholars from Poland, Czechoslovakia, and the Soviet Union, as well as Western scholars, and served as an important medium of international intellectual communication.

Mayenowa initiated and played an active editorial role in the dictionary of 16th-century Polish, which has reached volume 31 (volume 1 appeared in 1966), and she was similarly responsible for a series of editions of Polish literary texts, the *Library of Polish writers,* covering works from the middle ages to the 17th century with extensive explanatory lexicographic and grammatical apparatus. Through such editorial and organizational work, and through her formal and informal didactic activity (including the weekly colloquia that she held at her Warsaw apartment), Mayenowa trained and inspired a whole pleiad of younger scholars, including the Polish-born Australian semanticist Anna Wierzbicka, the Lublin linguist and folklorist Jerzy Bartmiński, the Warsaw lexicologist Zygmunt Saloni, and the late medievalist and versologist from Wrocław University, Jerzy Woronczak.

Mayan Languages

J M Maxwell, Tulane University, New Orleans, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mayan language family traditionally stretched from what is now northern El Salvador and Honduras, through Guatemala and Belize, and up to the southern states of Mexico, including Chiapas, Quintana Roo, Campeche, Yucatán, and part of La Huasteca. Today the family is more dispersed due to out-migration. Large colonies of Mayan speakers can be found in Los Angeles and other California communities, Arizona, Texas, and Florida. Most linguistic descriptions recognize 31 Mayan languages, including the extinct Chikomulselteko (Chicomuceltec). Most historical linguists posit the Maya homeland as the Cuchumatán peaks of Guatemala, the area with the greatest linguistic diversity today (Kaufman, 1976; Campbell, 1977; Fox, 1978; Campbell and Kaufman, 1983, 1985). The model of diversification correlates phonological, morphological, and syntactic changes with a least-moves model of out-migration, seeking confirmation in the archaeological method. Based on these reconstructions, Proto-Maya, the mother language from which the modern diversity springs, would have been spoken approximately 41 000 years ago. People began to migrate outward, sharing innovations as they moved.

The family eventually split into four divisions. (Note that many of the names of Mayan languages have a variety of spellings. These spellings reflect not only the writing traditions of various authors (English, Hispanic, Mayan), but also their political orientation. In Guatemala, particularly, Mayans have fought for and won official recognition of their own orthographies. In Chiapas, Mayan educators have also elected non-Spanish-based spelling systems. In Yucatán, however, a long tradition of literacy in Maya Yucateco has militated against changing orthographies. The spellings used in this article reflect the local practice.)

1. Wasteko, composed today only of Wasteko (Huasteco).
2. Yucatecan, composed of Maya Yucateco (Yucatán Maya), Mopan (Mopán Maya), Itzaj (Itzá), and Lakantun (Lacandán).
3. Western Division, broken into two branches: Ch'olan and Q'anjob'alan. The Ch'olan branch in turn has two subgroups, Ch'olan Proper, consisting of Chontal, Ch'ol, and Ch'orti' (Chortí), and Tzeltalan, consisting of Tzotzil and Tzeltal. The Q'anjob'al branch has two subgroups, Chujean, consisting of Tojolab'al and Chuj, and Q'anjob'alan Proper, consisting of Q'anjob'al (Eastern Kanjobal), Akateko (Western Kanjobal), Popti' (formerly Jakalteko (Jacalteco)), and Mocho' (Mochó).
4. Eastern Division, which is subdivided into the Mamean and K'iche'an subgroups. The Mamean branch is broken into Mam Proper, consisting of Mam and Teko (also called Tektiteko (Tectiteco)), and Ixilan, which includes Ixil (Nebaj Ixil) and Awakateko (Aguacateco). The K'iche'an branch includes the outliers Uspanteko (Uspanteco) and Q'eqchi' (Kekchí) and two major subdivisions, K'iche'an Proper, consisting of K'iche' (Quiché), Achi', Kaqchikel (Central Cakchiquel), Tz'utujiil (Tzutujil), Sakapulteko (Sacapulteco), and Sipakapense (Sipacapense), and Poqom, consisting of Poqomchi' (Pocomchí) and Poqomam (Pocomam).

Within subgroups there is a high degree of mutually intelligibility and multilingualism (particularly

Table 2 Mexican population figures

Language	*Government census figures, 2000*[a]	*Summer Institute in Linguistics*
Tzeltal, K'op	547 000	300 000 (1993)
Tzotzil, B'atzil K'op	514 000	225 000 (1990)
Mocho	500	>1000 (1993)
Lakantun, Hach T'an	130	
Tojolab'al, Tojowinik Otik	74 000	
Chontal	72 000	
Ch'ol	274 000	
Yucateco	1 490 000	

[a]The Mexican census also lists the numbers of speakers of 'Guatemalan' languages now resident in Mexico: Chuj 3900, Jakateko (Popti', Ab'xab'al) 1300, Q'eqchi' 1700, K'iche' 640, Kaqchikel 610, Ixil 310, Awakateko 60, Teko 50.

evident in market contexts), which blurs language and dialect boundaries. Often the divisions between language groups are determined more by political divisions and historical identities than by isoglosses. Rivalry between families in Aguacatán brought about the splintering of Awakateko, spawning a new 'language,' Chalchiteko, which won official recognition in Guatemala in 2003. Likewise, historic autonomy and a tradition of armed and political conflict between Q'umarkaaj (the K'iche' capital) and Rab'inal (the Achi' center) have created localized identities, which override mutual intelligibility in determining the language boundaries between the two groups. Residents of San Miguel Acatán and San Rafael La Independencia have traditionally considered themselves Q'anjob'al speakers, but the official recognition of Akateko as a language, with its own representation in the Academy of Mayan Languages of Guatemala, has served to accentuate linguistic differences and has discouraged use of educational materials, more widely available in Q'anjob'al. On the other hand, Mam, one of the four largest Guatemalan Mayan languages, and Chuj, spoken in northwestern Guatemala, both have deep internal dialectal splits. Dialects may differ in more that 20% of their core vocabulary, undergo different syntactic processes, and allow different sentential word orders, yet these languages maintain a shared identity.

Estimates of number of speakers are also highly political. Despite official rhetoric praising the ethnic richness of their countries, both Guatemala and Mexico have traditionally promoted assimilation to a national identity that is indigenous only ancestrally. (Also, El Salvador does not recognize any modern Maya as traditional ethnicities, although it does again host Mayan populations displaced by the genocidal

Table 3 Sample verbs in Kaqchikel

First-person plural	*Gloss*	*Second-person plural*	*Gloss*
xojwa'	'we ate'	xixwa'	'y'all ate'
x*ix*qaq'etej	'we hugged y'all'	x*oj*iq'etej	'y'all hugged us'

State	*Gloss*	*Intransitive*	*Gloss*	*Transitive*	*Gloss*
wa'li	'standing'	wa'ee	's/he stands'	twa'b'in	's/he stood her/him up'
xhjewli	'twisted'	xhjewee'	'it twists'	txhjewb'in	'she/he twists it'

war in Guatemala, 1960–1995. Honduran populations until recently were counted as Spanish speaking, although in the north there were ethnically Ch'orti' peoples; in the 2001, some Honduran rural schools began limited bilingual education, although without materials.) Leopoldo Tzian (1994) points out that official governmental censuses in Guatemala consistently underestimate the number of Mayas compared to surveys done by linguists, by international development agencies, and by health workers. Table 1 gives population figures for Guatemala: official census figures for the Mayan population (note the difference between ethnically identified Maya and those who speak their mother tongue), Tzian's data, the figures of AJPOPAB'CHI' (the Commission for the Officialization of the Indigenous Languages of Guatemala), and those of the Ministry of Education Survey for 2003. Table 2 contains population figures for Mexico, showing the official government figures (Instituto Nacional de Estadística, Geografía e Informática, 2000) and those of the Summer Institute in Linguistics (published 2004) with the date of the survey in parentheses. The first label under the rubric 'language' gives the traditional name for the language/ethnic group, used in most academic publications and in official documents prior to 2000, the second is the indigenous autodenomination.

Grammatical Characteristics

The Mayan Languages share many important characteristics, among these are ergativity, positionals, directional particles, and noun and numeral classifiers. These categories are developed in different ways in the various languages.

Ergativity

Ergative languages mark the relationship between the verb and its arguments with inflections that treat the subjects of intransitives and objects of transitive verbs as one category (marked by absolutive pronouns) and the subjects of transitives and possessors of nouns as a separate category (marked by ergative pronouns). Most of the Mayan languages show this system, with variations in subparts of the grammar, in which a nominative–accusative agreement pattern (like that Indo-European languages) surfaces. Such systems are referred to as split-ergative. Ch'orti' has a split-ergative system, with the change being triggered by subordination. In addition, Ch'orti' has a third pronominal set, which serves as prefixed subject markers of incompletive intransitive verbs. Table 3 shows sample verbs in Kaqchikel with subject pronouns in bold type and object pronouns in italics. Note the homology of intransitive subjects and transitive objects.

Positionals

Positionals are a special word class in Mayan languages, so-called because many denote positions such as 'standing,' 'lying prone,' and 'stuck crosswise in an opening.' However, some simply name conditions or states, such as 'wet,' 'naked,' and 'round.' Words that belong to this class have special derivational characteristics. The roots are inflected to form two or three types of nonverbal predicates (adjectives), intransitive verbs, and transitive verbs. Table 4 shows examples from Mam.

Some languages form reduplicated adjectives from the positional roots, for example, in Chuj *nhojanhojan* 'walk fluffily, like a shaggy sheep' and *linganlingan* 'be hanging.' Kaqchikel (Table 5), Tz'utujiil, and K'iche' copy the vowel of the root and the first consonant and then add a suffix for singular or plural agreement to form adjectives from positional roots.

Directional Particles

These particles, usually variants of intransitive verbs of motion, serve as a complement to main verbs. They may indicate actual movement of the actor or action, or they may add aspectual information. In Mam, transitive verbs almost always cooccur with a

Table 5 Reduplicated adjectives in Kaqchikel

State	*Gloss*	*Adjective*	*Gloss*
setesïk	'round, singular'	setesäq	'round, plural'
kotokïk	'crooked, singular'	kotokäq	'crooked'

Directional	*Gloss*	*Intransitive verb*	*Gloss*	*Phrasal use*	*Gloss*
ala	'out'	-il-	'leave'	xa'ila ala	'we go out, we leave'
aka	'in'	-ok-	'enter'	xah'oka aka	'we go in, we enter'
koon	'stay'	-kahn-	'stay, remain'	xahkahna koon	'we stay here'
pa	'thither'	-pan-	'arrive there'	xahpana pa	'we arrive there'
qa	'down'	-qaj-	'descend'	xahqaja qa	'we go down, we descend'

Table 7 Noun classifiers in Popti'

Classifer	*Objects in the class*	*Classifier*	*Objects in the class*
komam	Male supernaturals, diseases	komi'	Female supernaturals
ya'	Adult person	ho'	Young men
xo'	Young women	naj	Male, unknown, not respected
ix	Female, unknown, not respected	unin	Human baby
no'	Animals (other than the dog)	metx	Dog
te'	General plants and their products	ixim	Grains
tx'al	Cotton or synthetic thread	tx'anh	Fiber, string
q'ap	Cloth	tx'otx'	Earth, earthenware
ch'en	Metal, rock, mineral	atz'am	Salt
ha'	Water, liquid	q'a'	Fire

directional complement (see Table 6 for examples in Poqomam). Verb phrases in Yucatec, however, now rely on conjunction rather than complementation.

Noun Classifiers

These particles precede the nouns they modify and ascribe some property, social or material, to the noun. In the Q'anjob'alan group, noun classifiers are highly exploited by the grammar. They serve as definite articles and as pronouns. (See Table 7 for examples in Popti.') In the neighboring Mamean languages, the system is more attenuated. In K'iche'an languages, classifiers are used more as titles before names than as classifiers. In Yucatec, only morphological vestiges appear in names for a few plants and animals.

Numeral Classifiers

These may be of two types of numerical classifiers: suffixal, marking what kind of entity is being counted (Table 8), and independent, showing how the object counted is measured (Table 9). The suffixal type distinguishes three classes in Q'anjob'alan languages: people, animals, and other. Other Mayan languages have only trace suffixes, sometimes invariant in form.

Vocabulary

Mayan languages have borrowed words from many languages, including Nahuatl (Náhautl) (*masat* 'deer,' *tinamït* 'town,' in Kaqchikel), Spanish (*mexa* 'table,' *kaxtilanh winakhin* 'I'm a Spaniard, cock's crow,' in Chuj), and English (*tab'ana' klik pa ruwi' ruk'in ri maws* 'click on it with the mouse,' in Kaqchikel). They have also lent many words, for example, English *hurricane* < Kaqchikel *juraqän* '(lit.) one leg' and Spanish *makuy* < *majkuy* 'an herb.' New words are constantly developed with the contact of cultures and the implementation of new educational curricula. In Guatemala, the Academia de las Lenguas Mayas de Guatemala, an semi-autonomous branch of the government, is authorized to promote and develop the national languages. In Mexico, the federal government provides bilingual educational support and is supplemented by the efforts of the Academia de La Lengua Maya in Yucatán, Campeche, and Quintana Roo and by Sna Tz'ib'alom, the independent writers' cooperative in Chiapas.

Table 8 Popti' numeral classifier suffixes

Number root	*Gloss*	*Root with suffix*	*Gloss*
kanh-	'four'	kanhwanh	'four people'
waj-	'six'	wajk'onh	'six animals'
b'alunh-	'nine'	b'alunhe'	'nine things'

Table 9 Te'utujiil measure words[a]

Measure	*Gloss*	*Number root*		*Combined form*	*Gloss*
mooq'	'fistful'	ox-	'three'	oxmooq'	'three fistfuls'
quum	'sip'	kaj-	'four'	kajquum	'four sips'
tz'uur	'drop'	juu-	'one'	juutz'uur	'one drop'
seel	'slice, layer'	ka'-	'two'	ka'seel	'two slices'
peer	'plane surface'	waq-	'six'	waqpeer tz'alam	'six planed boards'
raab'	'long, cylindrical'	wuq-	'seven'	wuqraab' kolo'	'seven ropes'

[a]Note that the measure word or classifier serves as the base. The number is prefixed in an abbreviated combinatorial form.

Mayotte is the easternmost of the four islands that form the Comorian archipelago halfway between the east African coast and the northern tip of Madagascar. Actually Mayotte consists of two islands, Grande Terre and Petite Terre, inhabited by more than 100 000 people.

In the referendum for independence in 1974, the majority on Mayotte voted for staying with France. Therefore, when the other three Comorian islands, Grande Comore (Ngazija/Shingazija), Mohéli (Mwali), and Anjouan (Ndzwani/Shindzwani), became independent in 1975, Mayotte remained a French overseas territory with the status of a *collectivité territoriale*. Despite many resolutions by the United Nations and the Organization of African Unity demanding a unified, independent Comorian

Mayenowa, Maria Renata (1910–1988)

R A Rothstein, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Maria Renata Mayenowa (née Gurewicz) was born on June 2, 1910, in Belostok, Russia (from 1919 Białystok, Poland) and died on May 7, 1988, in Warsaw. She studied Polish language and literature at Stefan Batory University in Wilno, graduating in 1932. After teaching for four years in a Jewish high school she returned to the university, earning her doctorate in May 1939. She worked as a teaching assistant at the university (after 1939 the Vilnius University in Soviet Lithuania) until the Nazi invasion of 1941. She survived the occupation in hiding in northern Lithuania.

After working as a librarian in the Białystok City Library in 1945, she spent the next five years in Prague, where her husband, Józef Mayen, was press-attaché at the Polish Embassy. In 1948 she was one of the cofounders of the Institute for Literary Studies of the Polish Academy of Sciences (IBL PAN); she served as deputy director of IBL from 1957 to 1968. She held the rank of professor at the academy and at Warsaw University from 1954 until 1968, when she was dismissed as a result of the 'anti-Zionist' campaign of that year. She remained active, however, as a scholar, editor, and organizer of scholarly activity to her very last days.

The main focus of Mayenowa's individual publications was a linguistically informed stylistics and poetics, summed up in her 1974 handbook *Theoretical Poetics: Questions of Language* (in Polish; second, enlarged and revised edition 1979), which she characterized as dealing with the question of "what in verbal messages (especially those belonging to literature) is determined by their linguistic character." (p. 5) Stylistics and poetics were also at the center of her work as editor and translator, which resulted in collective volumes with titles like *Tekst, język, poetyka* (Text, language, poetics); *Semantyka tekstu i języka* (The semantics of text and language); *Tekst i język: problemy semantyczne* (Text and language: semantic problems); *O spójności tekstu* (On textual coherence), as well as annotated collections of translations of French, Czech, and Russian works on stylistics. Several of the volumes were the result of the symposia that she organized in Warsaw; they brought together linguists and literary scholars from Poland, Czechoslovakia, and the Soviet Union, as well as Western scholars, and served as an important medium of international intellectual communication.

Mayenowa initiated and played an active editorial role in the dictionary of 16th-century Polish, which has reached volume 31 (volume 1 appeared in 1966), and she was similarly responsible for a series of editions of Polish literary texts, the *Library of Polish writers,* covering works from the middle ages to the 17th century with extensive explanatory lexicographic and grammatical apparatus. Through such editorial and organizational work, and through her formal and informal didactic activity (including the weekly colloquia that she held at her Warsaw apartment), Mayenowa trained and inspired a whole pleiad of younger scholars, including the Polish-born Australian semanticist Anna Wierzbicka, the Lublin linguist and folklorist Jerzy Bartmiński, the Warsaw lexicologist Zygmunt Saloni, and the late medievalist and versologist from Wrocław University, Jerzy Woronczak.

Mayan Languages

J M Maxwell, Tulane University, New Orleans, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mayan language family traditionally stretched from what is now northern El Salvador and Honduras, through Guatemala and Belize, and up to the southern states of Mexico, including Chiapas, Quintana Roo, Campeche, Yucatán, and part of La Huasteca. Today the family is more dispersed due to out-migration. Large colonies of Mayan speakers can be found in Los Angeles and other California communities, Arizona, Texas, and Florida. Most linguistic descriptions recognize 31 Mayan languages, including the extinct Chikomulselteko (Chicomuceltec). Most historical linguists posit the Maya homeland as the Cuchumatán peaks of Guatemala, the area with the greatest linguistic diversity today (Kaufman, 1976; Campbell, 1977; Fox, 1978; Campbell and Kaufman, 1983, 1985). The model of diversification correlates phonological, morphological, and syntactic changes with a least-moves model of out-migration, seeking confirmation in the archaeological method. Based on these reconstructions, Proto-Maya, the mother language from which the modern diversity springs, would have been spoken approximately 41 000 years ago. People began to migrate outward, sharing innovations as they moved.

The family eventually split into four divisions. (Note that many of the names of Mayan languages have a variety of spellings. These spellings reflect not only the writing traditions of various authors (English, Hispanic, Mayan), but also their political orientation. In Guatemala, particularly, Mayans have fought for and won official recognition of their own orthographies. In Chiapas, Mayan educators have also elected non-Spanish-based spelling systems. In Yucatán, however, a long tradition of literacy in Maya Yucateco has militated against changing orthographies. The spellings used in this article reflect the local practice.)

1. Wasteko, composed today only of Wasteko (Huasteco).
2. Yucatecan, composed of Maya Yucateco (Yucatán Maya), Mopan (Mopán Maya), Itzaj (Itzá), and Lakantun (Lacandán).
3. Western Division, broken into two branches: Ch'olan and Q'anjob'alan. The Ch'olan branch in turn has two subgroups, Ch'olan Proper, consisting of Chontal, Ch'ol, and Ch'orti' (Chortí), and Tzeltalan, consisting of Tzotzil and Tzeltal. The Q'anjob'al branch has two subgroups, Chujean, consisting of Tojolab'al and Chuj, and Q'anjob'alan Proper, consisting of Q'anjob'al (Eastern Kanjobal), Akateko (Western Kanjobal), Popti' (formerly Jakalteko (Jacalteco)), and Mocho' (Mochó).
4. Eastern Division, which is subdivided into the Mamean and K'iche'an subgroups. The Mamean branch is broken into Mam Proper, consisting of Mam and Teko (also called Tektiteko (Tectiteco)), and Ixilan, which includes Ixil (Nebaj Ixil) and Awakateko (Aguacateco). The K'iche'an branch includes the outliers Uspanteko (Uspanteco) and Q'eqchi' (Kekchí) and two major subdivisions, K'iche'an Proper, consisting of K'iche' (Quiché), Achi', Kaqchikel (Central Cakchiquel), Tz'utujiil (Tzutujil), Sakapulteko (Sacapulteco), and Sipakapense (Sipacapense), and Poqom, consisting of Poqomchi' (Pocomchí) and Poqomam (Pocomam).

Within subgroups there is a high degree of mutually intelligibility and multilingualism (particularly

Table 8 Popti' numeral classifier suffixes

Number root	*Gloss*	*Root with suffix*	*Gloss*
kanh-	'four'	kanhwanh	'four people'

Mayotte: Language Situation

W Full, University of Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Mayotte is the easternmost of the four islands that form the Comorian archipelago halfway between the east African coast and the northern tip of Madagascar. Actually Mayotte consists of two islands, Grande Terre and Petite Terre, inhabited by more than 100 000 people.

In the referendum for independence in 1974, the majority on Mayotte voted for staying with France. Therefore, when the other three Comorian islands, Grande Comore (Ngazija/Shingazija), Mohéli (Mwali), and Anjouan (Ndzwani/Shindzwani), became independent in 1975, Mayotte remained a French overseas territory with the status of a *collectivité territoriale*. Despite many resolutions by the United Nations and the Organization of African Unity demanding a unified, independent Comorian

archipelago, the political split still exists. In 2002 Mayotte received the increased status of a *collectivité départementale*. Because of financial support from France, the economic and social conditions on Mayotte are better than on the independent islands of the archipelago.

While the three other islands are linguistically very homogeneous, with one Comorian dialect per island, the situation on Mayotte is quite different. Although most people also use a form of Comorian as first language, there are two groups with other idioms. In the biggest town, Mamoudzou, and on Petite Terre, we find people of French or Creole origin who speak French as their first language. French is also the official language of Mayotte, and because its education system is better and more efficient than that of the other islands, the knowledge of French is generally more profound.

Mainly in the western and southern part of Mayotte, a Sakalava (Bushi) dialect of Malagasy, the national language of Madagascar, is spoken in some towns and villages. These people are descendants of immigrants from Madagascar who arrived on Mayotte in the 19th century. They were culturally assimilated to a large extent but retained their original language.

The most widespread Comorian dialect on Mayotte is Shimaore, which shows greater regional differences than the other dialects do. The 'purest' Shimaore is spoken in the west and south of the island, whereas in the northeast many immigrants from Anjouan have affected the language spoken there. Generally, Shimaore and Shindzwani from Anjouan are the two Comorian dialects that are linguistically closest to one another (phonologically, lexically, and morphologically).

In the west and south of Mayotte are also two small enclaves (with two settlements each) where mainly descendants of immigrants from Grande Comore live. Parts of their language, such as verbal morphology, have preserved the Shingazija character while others, like lexicon or nominal morphology, have been clearly influenced by the surrounding Shimaore. Today their language is so different from the other dialects that it must be regarded as an independent dialect within Comorian. I have named it Shikombani after the main settlement. Linguistically its position on the continuum of Comorian dialects is in the middle between Shingazija on the one hand and Shindzwani/Shimaore on the other hand, sharing this position with Shimwali, the dialect on Moheli.

Mayrhofer, Manfred (b. 1926)

R Schmitt, Laboe, Germany

© 2006 Elsevier Ltd. All rights reserved.

Manfred Mayrhofer, one of the most eminent Indo–European and Indo–Iranian scholars of our time, was born on September 26, 1926 in Linz (Austria). After completing his secondary education in 1944 and being held as a prisoner of war for several months, he matriculated at the University of Graz, studying German language and literature in the winter term of 1945–1946. He soon turned, however, to Indo–European comparative grammar and to Indo–Iranian and Semitic studies. Later, he admitted being an autodidact of those fields in many respects. In 1949, he obtained his doctorate, and two years later he qualified as a lecturer in Indo–European linguistics and Indo–Iranian philology. In 1953, he was offered a position at the University of Würzburg, where he continued to teach as a lecturer and finally was appointed full professor of comparative linguistics in 1958. After a 4-year interlude as professor of comparative Indo–European linguistics and Indo–Iranian studies at the University of the Saarland in Saarbrücken, from 1962 to 1966, he went back to his native Austria and was appointed to the chair of

archipelago, the political split still exists. In 2002 Mayotte received the increased status of a *collectivité départementale*. Because of financial support from France, the economic and social conditions on Mayotte are better than on the independent islands of the archipelago.

Mayrhofer, Manfred (b. 1926)

R Schmitt, Laboe, Germany

© 2006 Elsevier Ltd. All rights reserved.

Manfred Mayrhofer, one of the most eminent Indo–European and Indo–Iranian scholars of our time, was born on September 26, 1926 in Linz (Austria). After completing his secondary education in 1944 and being held as a prisoner of war for several months, he matriculated at the University of Graz, studying German language and literature in the winter term of 1945–1946. He soon turned, however, to Indo–European comparative grammar and to Indo–Iranian and Semitic studies. Later, he admitted being an autodidact of those fields in many respects. In 1949, he obtained his doctorate, and two years later he qualified as a lecturer in Indo–European linguistics and Indo–Iranian philology. In 1953, he was offered a position at the University of Würzburg, where he continued to teach as a lecturer and finally was appointed full professor of comparative linguistics in 1958. After a 4-year interlude as professor of comparative Indo–European linguistics and Indo–Iranian studies at the University of the Saarland in Saarbrücken, from 1962 to 1966, he went back to his native Austria and was appointed to the chair of

general and Indo–European linguistics at the University of Vienna, which had a worldwide reputation from the time of Friedrich Müller and Paul Kretschmer. Since his retirement in 1988, he has lived as a professor emeritus in Vienna. He is a member of more than a dozen academies of sciences and was particularly active in the Austrian Academy of Sciences, not only as a member of the Committee from 1970 to 1982.

Mayrhofer is the author of a large number of manuals, dictionaries, other monographs, articles, and reviews (for a full bibliography up to 1995, see Schmitt, 1979–1996), not only in the field of Indo–Iranian linguistics and onomastics, but also general Indo–European studies and the history of this discipline. He is one of the most prolific linguists of our time, and in an autobiographical sketch (1991) he characterized himself as an enthusiastic writer of manuals (*begeisterter Handbuch-Schreiber*).

Mayrhofer's *magnum opus*, and actually his lifework, is the etymological dictionary of Old Indo–Aryan; more exactly, his two etymological dictionaries of this language. Beginning during his student days, he gathered material for such a piece of work, the publication of which began when he reached the age of 25. It was finally completed in four volumes in 1980. As the publication went on, the conception of the *Kurzgefaßtes etymologisches Wörterbuch des Altindischen/A Concise Etymological Sanskrit Dictionary* (1956–1980), which originally had been planned as a rather succinct outline, changed radically, and the dictionary became more and more detailed and informative. As a result of decades of practical experience and of thorough considerations about writing an etymological dictionary of such a richly attested language, Mayrhofer began, immediately after the completion, to work out an entirely novel successor work, the *Etymologisches Wörterbuch des Altindoarischen* (1992–2001). This book had nothing in common with its predecessor but its author and subject matter. Here, he introduced into etymological research of Old Indo–Aryan a sharp differentiation between the words attested already in (more ancient) Vedic literature, and those of the younger language, (Sanskrit proper) documented not earlier than the two great epics for the first time. Those two layers of the vocabulary differ to a large extent in the principal sources of the words themselves, for the older, already Vedic part of the lexicon mainly consists of inherited words (going back to Indo–Iranian and Indo–European). Among the words that appear for the first time only in later centuries, there is a great number of loan words borrowed from either the Middle Indo–Aryan vernaculars (Prakrits), or from non-Aryan languages. As a supplement to this dictionary, in a sense anyway, Mayrhofer most recently published a monographic study on the personal names attested in the Rig-Veda, to which were added the names of the poets of the Rig-Vedic hymns (2003). With this, he drew attention to a long-neglected field, which would deserve intensive efforts by future scholars.

He did other work in the field of Indo–Aryan linguistic history, beginning with the linguistic remains of the early Indo–Aryans in the 2nd millennium Ancient Near East (1966). Likewise, he also treated problems of the alleged Dravidian and Austro-Asiatic substratum influences in the Old Indo–Aryan lexical stock, which he viewed recently, however, in a more and more skeptical way.

The first major contribution of Mayrhofer's in the field of the Old Iranian languages was the etymological glossary, which he contributed to the 1958 Spanish and, together with the morphological section, to the later German versions of the *Handbuch des Altpersischen* (Brandenstein and Mayrhofer, 1964), which his teacher Wilhelm Brandenstein had begun. This glossary was a milestone, insofar as it was the first Old Persian dictionary to also contain the vocabulary attested (outside the royal inscriptions themselves) in the so-called collateral tradition of Elamite, Aramaic, and other non-Iranian sources. By that and by several subsequent reports on current research, he got more and more involved in anthroponomastic studies, which in Old Iranian are of crucial importance for etymological reasons.

In 1973, he published a most careful interim analysis of the (mostly Old Iranian) personal names attested in the Elamite cuneiform tablets excavated in Persepolis and belonging, for the most part, to the heyday of the Achaemenid Empire under Darius I (and more exactly to the years 509–494 B.C.). Previously, in 1969, Mayrhofer had initiated the *Iranisches Personennamenbuch* as a large-scale project of the Austrian Academy of Sciences. Someday it will replace Ferdinand Justi's age-old *Iranisches Namenbuch* (1895), which over the course of time became somewhat obsolete, owing to the enormous increase in linguistically Iranian onomastic material. He himself prepared the first volume (after which several others followed, and many more will follow in the future), treating the names attested in the Avesta and in the Old Persian inscriptions (Mayrhofer, 1977–1979).

After having taken over the editorship of the *Indogermanische Grammatik*, founded by Jerzy Kuryłowicz, Mayrhofer prepared a systematic account of the phonology of the Indo–European proto-language (1986), which took into consideration all the particulars and subtleties of the laryngeal theory as well. This book became his most important

contribution to Indo–European studies in general. Moreover, a rather characteristic feature of his research is that he also has a keen interest in problems of the history of Indo–European studies in the 19th and 20th centuries. He once dealt with the question of how reconstructing the Proto-Indo–European phonological system left step-by-step the original Sanskrit-like notation (Mayrhofer, 1983), and two years before that he had investigated the reception of Ferdinand de Saussure's seminal ideas and theories by today's Indo–Europeanists (Mayrhofer, 1981).

Mayrhofer's writings stand out for their admirable acquaintance with all the relevant specialist literature and for their careful and balanced judgment. They clearly show that he is capable of presenting even the most complicated matters and theories with didactic skill and in a clear, concise, and quite agreeable linguistic form.

One of the truly great figures of 20th-century linguistics, most famous as the champion of generative semantics, and a genuine libertarian/anarchist original, James Quillan McCawley Jr., was born in Glasgow, Scotland, on March 31, 1938, as the first child of James Quillan McCawley, a businessman, and Dr. Monica Bateman McCawley, a physician and surgeon. The family emigrated to the United States during World War II; first James Sr. went to Toronto and then to New York with his two brothers, finally settling in Chicago after the war when he was joined by his wife and children. James Jr., (later, on becoming a U.S. citizen, he changed his name to James David McCawley, jettisoning the Jr.) was soon recognized as a very bright student, skipping several grades while attending parochial grade schools and St Mel's High School. In his teenage years, he displayed an interest in and also started learning languages (so that during his linguistic career he was able to draw on a dozen or so languages).

In 1954, at the age of 16, he entered the University of Chicago and progressed rapidly towards the graduate school, where he received an M.S. in mathematics in 1958. Many years later he would say that it was for no particularly good reason that he went for mathematics, and in fact he was increasingly turned off by mathematics. He soon discovered linguistics through a course taught by Eric Hamp. He accepted a Fulbright fellowship to study mathematics and logic at the Westfälische Wilhelms University in Münster,

contribution to Indo–European studies in general. Moreover, a rather characteristic feature of his research is that he also has a keen interest in problems of the history of Indo–European studies in the 19th and 20th centuries. He once dealt with the question of how reconstructing the Proto-Indo–European phonological system left step-by-step the original Sanskrit-like notation (Mayrhofer, 1983), and two years before that he had investigated the reception of Ferdinand de Saussure's seminal ideas and theories by today's Indo–Europeanists (Mayrhofer, 1981).

Mayrhofer's writings stand out for their admirable acquaintance with all the relevant specialist literature and for their careful and balanced judgment. They clearly show that he is capable of presenting even the most complicated matters and theories with didactic skill and in a clear, concise, and quite agreeable linguistic form.

One of the truly great figures of 20th-century linguistics, most famous as the champion of generative semantics, and a genuine libertarian/anarchist original, James Quillan McCawley Jr., was born in Glasgow, Scotland, on March 31, 1938, as the first child of James Quillan McCawley, a businessman, and Dr. Monica Bateman McCawley, a physician and surgeon. The family emigrated to the United States during World War II; first James Sr. went to Toronto and then to New York with his two brothers, finally settling in Chicago after the war when he was joined by his wife and children. James Jr., (later, on becoming a U.S. citizen, he changed his name to James David McCawley, jettisoning the Jr.) was soon recognized as a very bright student, skipping several grades while attending parochial grade schools and St Mel's High School. In his teenage years, he displayed an interest in and also started learning languages (so that during his linguistic career he was able to draw on a dozen or so languages).

In 1954, at the age of 16, he entered the University of Chicago and progressed rapidly towards the graduate school, where he received an M.S. in mathematics in 1958. Many years later he would say that it was for no particularly good reason that he went for mathematics, and in fact he was increasingly turned off by mathematics. He soon discovered linguistics through a course taught by Eric Hamp. He accepted a Fulbright fellowship to study mathematics and logic at the Westfälische Wilhelms University in Münster,

Germany in 1959 and 1960, but instead of doing mathematics, he started taking all kinds of language courses there. This continued on his return to Chicago, where he fell in love with Japanese. He learned about the new graduate program in linguistics being started at the Massachussets Institute of Technology (MIT) and applied for it, spending three years in the first Ph.D. class there. He worked as a research assistant at MIT's Mechanical Translation Group from 1962 to 1963, leaving to study Japanese at Seton Hall in 1963 and to do research at the IBM Watson Center in Yorktown Heights in 1964. His Ph.D. dissertation on the accentual system of modern standard Japanese, submitted in 1965, was supervised by Noam Chomsky. He returned in 1964 to the University of Chicago as an assistant professor of linguistics, where he spent the remainder of his career, except for numerous travels as visiting professor. He was tenured in 1969 as an associate professor and was promoted to full professor in 1970. He married linguist Noriko Akatsuka in 1971, their marriage ending in an amicable divorce in 1978. He died on April 10, 1999.

McCawley's general philosophy may be said to be characterized by consistency across epistemology (science) and praxeology (politics, economics, and ethics), vision being matched by sensitivity to empirical details and data. Although McCawley is chiefly known as a syntactician and semanticist, he clearly resists such ready-made classificatory labels as he was also a phonologist, morphologist, lexicologist, logician, epistemologist, and pragmaticist (besides being a passionate musicologist and a culinary artist).

He first became widely known with his 1968 paper, where he proposed what can be seen in retrospect as a first draft of generative semantics. This movement suited him very well because it was compatible with his background in mathematics and logic, and its arguments were data-driven. He characterized his approach as a revisionist version of transformational grammar, centering on some ideas of transformational grammar that he considered to be fruitful, such as constituency, multiple syntactic strata, and the cyclic principle.

McCawley clearly disagreed with generative linguists regarding the autonomy of linguistics, especially syntax. For him it was impossible to do any syntax without crossing area and disciplinary boundaries. In his framework, syntactic phenomena constituted primarily dependent variables, to be explained as epiphenomena caused by interactions of such independent variables as semantics and pragmatics, as well as morphology and the lexicon. In a very important paper, entitled *An un-syntax*, McCawley claimed that "much of what has been thought of as syntax is largely a reflection of other things, such as morphology, logic, production strategies, and principles of cooperation" (1981b: 168). This insight actually epitomized all of his work.

He kept revising his model incrementally, adding more and more rules and thus extending its reach to accommodate more and more phenomena, until it reached its zenith in *The syntactic phenomena of English* (1988, 2nd edn., 1998), a reference full of details about English grammar that have always wanted more attention from linguists. Along with his logic book (*Everything that linguists have always wanted to know about logic* (*but were ashamed to ask;*) 1981a, 2nd edn., 1993), this was no doubt among his most enduring contributions to the pool of classical linguistic literature. They were eclectic references that synthesize the most significant findings by himself and other linguists about semantics, syntax, pragmatics, and the philosophy of language during his career. Both books were constructive proof that generative grammar can be used to produce sane descriptive statements about language.

McDavid, Raven I., Jr (1911–1984)

W Viereck, Universität Bamberg, Bamberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Raven Ioor McDavid, Jr. was born in Greenville, South Carolina, in 1911. In 1931 he graduated from Greenville's Furman University. In graduate school at Duke University he specialized in Milton, receiving his Ph.D. in 1935 with a dissertation on Milton as a political thinker. The following year McDavid taught at a military college in Charleston. In 1937 he participated in the Second Linguistic Institute, taught by famous scholars in the field such as Leonard Bloomfield, Edward Sapir, Hans Kurath, and Bernard Bloch; the latter discovered in McDavid an aptitude for phonetics. Here he was also introduced to H. L. Mencken's *American language*. The Linguistic Institute was the strongest impetus to McDavid's career. He began to study American English as it was then spoken, an activity only interrupted during the World War II years, when he was called upon to do war-related work. He then studied Burmese and also worked on a dictionary of spoken Chinese.

From 1945 to 1950 McDavid conducted over 500 interviews for the *Linguistic atlas* project at Kurath's request – first on the Atlantic seaboard and then in the north central states. These investigations, which he had begun as early as 1941, led to his life's work of linguistic geography. In 1952 McDavid finally found a regular teaching position at Western Reserve, and in 1957 he went to the University of Chicago, where he became full professor of English and linguistics in 1964, a position he occupied until his retirement in 1978.

Mencken's *American language* was instrumental in changing McDavid's interest from literature to language. In 1963 he published a one-volume abridged edition of this influential book with annotations and modifications reflecting developments after 1948.

McDavid is best known for his work in linguistic geography, both regional and social. The first major outcome of his work in this field was *The pronunciation of English in the Atlantic states* (1961), written together with Kurath. Moreover, McDavid was editor-in-chief of a number of American regional linguistic atlases. Lexicography, an interest of McDavid's dating back to his dictionary work during the war years, attracted his attention again later in his career. Among other areas, he investigated the prepublication criticism of the controversial *Webster's third*.

McDavid was no doubt the leading researcher in American English speech patterns. He made a significant contribution not only to traditional dialectology, but also to the study of social variation. Without him, variationists could not have made their advances.

McLuhan, Marshall (b. 1911)

R Chatterjee, Lado International College, Silver Spring, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Herbert Marshall McLuhan, a professor at the University of Toronto for most of his active life, was born July 21, 1911, in Edmonton, Alberta. After his college years in Canada, he entered the University of Cambridge for higher studies in English. At an early stage, McLuhan found himself absorbed in James Joyce, Giambattista Vico, and G. K. Chesterton. At Cambridge, he studied and worked closely with I. A. Richards, author of *Practical criticism,* and, with C. K. Ogden, of *The meaning of meaning*. McLuhan was also deeply interested in William Blake's work. He converted to Roman Catholicism in 1937, later emphasizing the connection between his readings in religion and his media study (Gordon, 1997: 75).

Marshall McLuhan achieved distinction as a critic and analyst of the media. His aim on leaving Cambridge after the completion of his studies has been described as 'the training of perception,' an activity compatible with Cambridge criticism in general.

McLuhan saw media (e.g., phonetic writing, radio) as extensions of the human body and the nervous system, an idea originating in the work of his friend Harold Innis (Gordon, 1997: 148), to which he was much indebted. From Innis too came the idea that print creates nationalism.

The slogan 'the medium is the message' is universally associated with McLuhan. Its meaning has been much expounded and debated. In a letter to David Segal, McLuhan wrote: "Major insight on 'medium is the message' is this: each new technology, be it house, or wheel, or radio, creates a new human environment" (1964). Here it is notable that McLuhan thought of language as mankind's first technology. He was concerned with the question, 'How can we escape the inevitable changes that new technologies bring?' Before escape, the changes have to be understood. Commentators list some 10 different ways in which media have an impact on the human being and the environment.

McLuhan classified media like TV and radio into two groups, 'hot' and 'cool.' Hot media are 'high definition,' meaning they are loaded with information, leaving little for the user to do, and include radio, print, and movies, in contrast to cool media like telephone, speech, and TV respectively. He expressed the 'laws of media' as a tetrad. For example, e-mail (1) **extends** writing, (2) **renders obsolete** long-distance phone calls, (3) **retrieves** the telegram (gives it a new, intensified form) and (4) **reverses into dialogue** when writers are online together (Gordon, 1997: 341).

McLuhan's literary training aided his richly metaphoric thinking about media. Among linguists, he read Saussure and Whorf closely. It is debated whether his reading of the former is more correct than Jacques Derrida's postmodern one. Since the 1990s, critical works on McLuhan have appeared. An early challenging and dismissive work is Jonathan Miller's *McLuhan*.

Mead, George Herbert (1863–1931)

N Denzin, University of Illinois at Urbana–Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

George Herbert Mead was a leading figure in American pragmatic philosophy, along with William James, Charles Sanders Peirce, and John Dewey. Mead never published a finished version of his theories, and his ideas and lectures were gathered together by students in several posthumous publications, including *The philosophy of the present* (1932), *Mind, self, and society* (1934), *Movements of thought in the nineteenth century* (1936), *The philosophy of the act* (1938), *George Herbert Mead on social psychology* (1956), *Mead: selected writings* (1962), and *The individual and the social self: the unpublished work of George Herbert Mead* (1982). These works have figured centrally in the American school of sociology called symbolic interactionism.

The son of a New England clergyman and a mother who would later become president of Mt. Holyoke College, Mead graduated from Oberlin College in 1883. From 1887 to 1888, he did graduate work in philosophy and psychology at Harvard University, studying under William James (he lived in the James's house and tutored their children), Josiah Royce, and George Herbert Palmer. From 1888 to 1891, Mead studied in Berlin and Leipzig, where he came into contact with Wihelm Wundt's work on linguistics and physiological psychology and met G. Stanley Hall, who had studied with Wundt. On October 1, 1891, in Berlin, Mead married Helen Castle of the rich landowning Castle family of Honolulu, Castle and Cooke. In the same year, Mead returned to the United States (without a Ph.D.) and took a position in the philosophy department at the University of Michigan, where John Dewey, James Tufts, and Charles Horton Cooley were teaching.

Mead followed Dewey to the University of Chicago in 1891, where he remained until his death on April 26, 1931. With Dewey, Angell, and Tufts, he played a major part in the formation of what he called the Chicago School of philosophy. Mead taught a variety of courses at Chicago, including Social Psychology, Movements of Thought in the Nineteenth Century, the Philosophy of Eminent Scientists, French Philosophy, Aristotle, Hume, Hegel, Leibniz, German Romanticism, Ethics Problems in the Theory of Relativity, and Whitehead. Mead's course in social psychology was a major influence on Chicago-trained sociologists, including Ellsworth Faris, Robert Park, and Ernest Burgess. After he died, this course was taken over by Herbert Blumer, who would, in 1937, coin the phrase 'symbolic interaction' to describe Mead's unique approach to social psychology.

Five terms were central to Mead's social psychology: gesture, symbol, self, mind, and act. Mead developed a theory of mind and self that did not regard these phenomena as antecedents to society and social behavior. He argued that the self arises out of the human's ability to use language in a way that permits the perspective of the other to be entered into. The self consists of two parts, the 'I' and the 'me.' The 'I' is the subjective source of action, of the impulse to act in a situation. The 'me' consists of the attitudes of the other who is taken into account as the 'I' thinks and acts. The self is a social process involving constant symbolic interaction between the 'I' and the 'me' phases of experience. The self emerges through three stages of development called the play, the game, and the generalized other phases. In each phase, the person is better able to take the collective attitudes of the other toward their action in a concrete situation. Mind is a social process. It involves the use of gestures and symbols that call out in the person meanings that are shared with others. A triadic process structures the conferral of meaning on a thing: a gesture signifies action to another, it signifies what the person making the gesture plans to do, and it signifies what the person making the joint action that is to occur for both parties in the situation plans to do.

Human experience is not a continuous flow but is organized in terms of social acts. Acts have three phrases. Acts arise out of problematic situations in which ongoing activity is blocked. Phase one is the perception of the problematic situation (e.g., 'I am hungry'). Phase two is the manipulation phase. The person moves to resolve the problematic situation by acting on an object (e.g., preparing a meal). Phase three is consummation. The act is brought to completion (e.g., eating the meal). In each phase of the act, different phases of the self (the 'I' and the 'me') are experienced.

Mead argued that the "supreme test of any present-philosophy ... must be found in its interpretation of experimental science" (*Philosophy of the act*, 1938: 505). By experimental science, he meant several things, including modern physics (as reworked by Whitehead), Darwinian naturalism, and Dewey's instrumentalism (as given in Dewey's *Essays in experimental logic*). Mead argued that a scientist must have a clearly formulated problem, or hypothesis, and a clear method of determining if a hypothesis is

confirmed or disconfirmed. The scientist works through the three phases of the act in the resolution of a scientific problem. Scientists must have a procedure that does not allow them to enter into the situation in advance of experimental inquiry. Mead's pragmatism, or scientific method, was a version of Dewey's instrumentalism.

Mead remains a central figure in contemporary social theory and social psychology. His work has influenced the theories of Jürgen Habermas, Anthony Giddens, and Anselm Straus, for example. Mead's works are still topics of empirical investigation and philosophical and theoretical controversy (Blumer and Miller, 2004).

Meaning Postulates

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Carnap (1956: 225) proposed that meaning postulates are relative to a purpose, for instance:

> Suppose [a man constructing a system] wishes the predicates '*Bl*' and '*R*' to correspond to the words 'black' and 'raven'. While the meaning of 'black' is fairly clear, that of 'raven' is rather vague in the everyday language. There is no point for him to make an elaborate study, based either on introspection or on statistical investigation of common usage, in order to find out whether 'raven' always or mostly entails 'black.' It is rather his task to make up his mind whether he wishes the predicates '*R*' and '*Bl*' of his system to be used in such a way that the first logically entails the second. If so, he has to add the postulate
>
> (P_2) '$(x)\ (Rx \supset Bl\ x)$'
>
> to the system, otherwise not.

Given P_2 nothing can be a raven that is not black. If the system is a semantic metalanguage for English, then (according to Carnap) it is analytically true that (x[raven′(x) → black′(x)] (to use a different, but equivalent formulation). One may dispute the choice of example (*to be raven-haired* is to have black hair, but an observed raven may be albino); yet the method for introducing nonlogical vocabulary into formal semantics seems appropriate. For instance it is generally agreed that something like (1) and (2) are valid:

(1) $\forall x \forall y[\text{kill}'(x,y) \rightarrow \text{cause}'(x,(\text{become}'(\neg(\text{alive}'(y)))))]$

(2) $\forall x[\lambda x[\text{bull}'(y) \wedge \text{animal}'(y)](x) \rightarrow \text{male}'(x)]$

The predicates kill′, cause′, bull′, etc. are nonlogical vocabulary treated as semantic primitives.

The stipulation of meaning postulates for any given language is problematic. There is no consensus over what constitute the set of semantic primitives for any language. There is the problem of correspondence between the metalanguage and the object language (e.g., between kill′ and *kill*). There is often a problem determining which the necessary semantic relations are and which are the contingent ones. For instance, one might question how the figurative killing of fires or conversations can be accommodated with (1). (2) is valid for papal bulls, male calves, male elephants, male whales, male seals, and male alligators; but how is it to be extended to incorporate the default reference to an adult bovine?

Fodor (1998) and elsewhere has argued against meaning postulates (which he supported in Fodor *et al*., 1975). In part his argument is that lexical meanings are not compositional for words like *kill* and *bull*. But there is no reason to insist that the right-hand side of the arrow in either (1) or (2) represents part of the semantic composition of the left-hand side. It simply shows a valid relation between structures containing some semantic primitives. Fodor also adopted Quine's (1953) objections to analyticity and claims that no principled distinction can be drawn between meaning postulates and encyclopedic knowledge. Determining what is semantic and what encyclopedic is a knotty problem we cannot resolve here (see Allan, 2001 for a discussion). Horsey (2000) marshals several arguments against Fodor's position. Meaning postulates remain a useful device for semantics.

confirmed or disconfirmed. The scientist works through the three phases of the act in the resolution of a scientific problem. Scientists must have a procedure that does not allow them to enter into the situation in advance of experimental inquiry. Mead's pragmatism, or scientific method, was a version of Dewey's instrumentalism.

Mead remains a central figure in contemporary social theory and social psychology. His work has influenced the theories of Jürgen Habermas, Anthony Giddens, and Anselm Straus, for example. For instance, one might question how the figurative killing of fires or conversations can be accommodated with (1). (2) is valid for papal bulls, male calves, male elephants, male whales, male seals, and male alligators; but how is it to be extended to incorporate the default reference to an adult bovine?

Fodor (1998) and elsewhere has argued against meaning postulates (which he supported in Fodor *et al*., 1975). In part his argument is that lexical meanings are not compositional for words like *kill* and *bull*. But there is no reason to insist that the right-hand side of the arrow in either (1) or (2) represents part of the semantic composition of the left-hand side. It simply shows a valid relation between structures containing some semantic primitives. Fodor also adopted Quine's (1953) objections to analyticity and claims that no principled distinction can be drawn between meaning postulates and encyclopedic knowledge. Determining what is semantic and what encyclopedic is a knotty problem we cannot resolve here (see Allan, 2001 for a discussion). Horsey (2000) marshals several arguments against Fodor's position. Meaning postulates remain a useful device for semantics.

Meaning, Procedural and Conceptual

D Blakemore, University of Salford, Greater Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

The distinction between procedural and conceptual meaning resulted from the attempt to reanalyze Grice's (1989) notion of conventional implicature in relevance theoretic terms, or, more generally, from the attempt to provide a cognitive reanalysis of the distinction drawn between truth conditional and non-truth conditional meaning (see Grice, 1989; *see* **Grice, Herbert Paul (1913–1988); Implicature**). However, soon after its introduction (Blakemore, 1987), it was shown that the relevance theoretic distinction was not coextensive with the distinction between truth conditional and nontruth conditional meaning, and thus represented a departure from the approach to semantics that underlies Grice's notion of conventional implicature. While there is a range of phenomena that can be analyzed in terms of the conceptual–procedural distinction, the emphasis in pragmatics has mostly centered on its application to the analysis of so-called 'discourse markers' (*see* **Discourse Markers**). It has to be said, however, that the term *procedural* is not always used in the same way, and that the distinction between conceptual and procedural encoding is not always drawn within a relevance theoretic framework. In argumentation theory, any expression which has an argumentative function is said to encode procedural meaning (Moeschler, 1989). According to this criterion, *because* is procedural; however, it is not procedural according to the relevance theoretic definition outlined below. Fraser (1996, 1998) has used the term *procedural* to describe the meaning of any expression with an indicating function, where *indicating* is intended in its speech act theoretic sense, in which it contrasts with *saying* or *describing*. Because the relevance theoretic distinction is not coextensive with the traditional distinction between truth conditional and nontruth conditional meaning, it is not surprising that there are expressions which are procedural according to Fraser but conceptual according to the relevance theoretic definition – e.g., *as a result*. This article will focus on the relevance theoretic distinction, showing, on the one hand, how it derives from a relevance theoretic view of linguistic semantics, and on the other, how the principle of relevance provides an explanation for the fact that languages have developed means for encoding procedures (*see* **Relevance Theory**). It will then turn to the way in which procedural encoding has been applied in the analysis of discourse markers or connectives, and the questions this type of analysis raises.

Relevance Theoretic Semantics

Grice's (1989) notion of conventional implicature was a means of maintaining a definition of *what is said* in which linguistic meaning coincides with truth conditional content. While he accepts that the suggestion carried by *therefore* in (1) is linguistically encoded, he does not wish to allow that in his "favoured sense of 'say,' one who utters (1) would have *said* that Bill's being courageous follows from his being a philosopher" (1989: 21):

(1) Bill is a philosopher and he is, therefore, brave.

Grice's solution to the problem posed by nontruth conditional linguistic meaning was to modify his definition of *what is said* so that it applied only to the performances of so-called *central* speech acts, and not to the performances of *noncentral* speech acts indicated by expressions such as *therefore* (*see* **Speech Acts; Speech Acts and Grammar**).

Meaning, Procedural and Conceptual

D Blakemore, University of Salford, Greater Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

The distinction between procedural and conceptual meaning resulted from the attempt to reanalyze Grice's (1989) notion of conventional implicature in relevance theoretic terms, or, more generally, from the attempt to provide a cognitive reanalysis of the distinction drawn between truth conditional and non-truth conditional meaning (see Grice, 1989; *see* **Grice, Herbert Paul (1913–1988); Implicature**). However, soon after its introduction (Blakemore, 1987), it was shown that the relevance theoretic distinction was not coextensive with the distinction between truth conditional and nontruth conditional meaning, and thus represented a departure from the approach to semantics that underlies Grice's notion of conventional implicature. While there is a range of phenomena that can be analyzed in terms of the conceptual–procedural distinction, the emphasis in pragmatics has mostly centered on its application to the analysis of so-called 'discourse markers' (*see* **Discourse Markers**). It has to be said, however, that the term *procedural* is not always used in the same way, and that the distinction between conceptual and procedural encoding is not always drawn within a relevance theoretic framework. In argumentation theory, any expression which has an argumentative function is said to encode procedural meaning (Moeschler, 1989). According to this criterion, *because* is procedural; however, it is not procedural according to the relevance theoretic definition outlined below. Fraser (1996, 1998) has used the term *procedural* to describe the meaning of any expression with an indicating function, where *indicating* is intended in its speech act theoretic sense, in which it contrasts with *saying* or *describing*. Because the relevance theoretic distinction is not coextensive with the traditional distinction between truth conditional and nontruth conditional meaning, it is not surprising that there are expressions which are procedural according to Fraser but conceptual according to the relevance theoretic definition – e.g., *as a result*. This article will focus on the relevance theoretic distinction, showing, on the one hand, how it derives from a relevance theoretic view of linguistic semantics, and on the other, how the principle of relevance provides an explanation for the fact that languages have developed means for encoding procedures (*see* **Relevance Theory**). It will then turn to the way in which procedural encoding has been applied in the analysis of discourse markers or connectives, and the questions this type of analysis raises.

Relevance Theoretic Semantics

Grice's (1989) notion of conventional implicature was a means of maintaining a definition of *what is said* in which linguistic meaning coincides with truth conditional content. While he accepts that the suggestion carried by *therefore* in (1) is linguistically encoded, he does not wish to allow that in his "favoured sense of 'say,' one who utters (1) would have *said* that Bill's being courageous follows from his being a philosopher" (1989: 21):

(1) Bill is a philosopher and he is, therefore, brave.

Grice's solution to the problem posed by nontruth conditional linguistic meaning was to modify his definition of *what is said* so that it applied only to the performances of so-called *central* speech acts, and not to the performances of *noncentral* speech acts indicated by expressions such as *therefore* (*see* **Speech Acts; Speech Acts and Grammar**).

However, as Sperber and Wilson (1995) and Carston (2002) have shown, the assumption that linguistic meaning coincides with the truth conditional content of the utterance cannot be justified, because the propositional content of utterances is underdetermined by their linguistic properties. While the thoughts communicated by utterances may have truth conditions, it cannot be said that linguistic form encodes thoughts. Linguistic meaning is an input to the pragmatically constrained inferential processes that use contextual information to deliver thoughts. The question for linguistic semantics, in this view, is not about the relationship between language and the world but about the relationship between linguistic form and the inferential processes that deliver thoughts (*see* **Pragmatics and Semantics**).

The distinction between conceptual and procedural encoding derives from the argument that if utterance interpretation involves the construction and inferential manipulation of propositional representations, then it is reasonable to expect two answers to this question. On the one hand, linguistic form can encode the constituents of the conceptual representations that take part in inferential computations, and on the other, it can encode information that makes particular kinds of computations salient. Consider (2a) and (2b), where (2b) could be interpreted as a contextual implication derived in an inference that has (2a) as a premise, or as a premise that has (2a) as a conclusion.

(2a) Tom will be late.
(2b) He is coming from London.

The claim that linguistic meaning can encode procedures is the claim that there are linguistic expressions e.g., – *so* or *after all* in this case – which guide the hearer to the inferential procedure that yields the intended interpretation.

Why Languages Develop Procedural Encoding

It has been argued that the fact that languages have developed expressions which constrain inferential procedures can be explained within relevance theory in terms of the communicative principle of relevance (Sperber and Wilson, 1995). According to this principle, a hearer who recognizes that a speaker has deliberately communicated with her is entitled to assume not just that the utterance is relevant enough (in terms of effects and effort) to be worth her attention, but that it is the most relevant utterance the speaker could have produced, given her interests and abilities. Because the degree of relevance is affected by the amount of processing effort required for the derivation of the intended cognitive effects, this means that the use of an expression that encodes a procedure for identifying the intended interpreted would be consistent with the speaker's aim of identifying relevance for a minimum processing cost.

Traugott and Dasher (2002) have argued that languages tend to develop procedural constraints on interpretation out of their existing conceptual resources. However, although they agree that there is a distinction between procedural and conceptual (or, as they call it, 'contentful') meaning, their account of how meaning change takes place is based on the assumptions of cognitive semantics and neo-Gricean pragmatics rather than on relevance theoretic pragmatics, and it is not clear that the distinction is drawn in the same way (*see* **Cognitive Linguistics; Neo-Gricean Pragmatics**). Moreover, their account assumes that meaning, changes results from the conventionalization of pragmatic inferences, where this is unpacked in (Gricean) terms of the conventionalization of the relation between a linguistic form and the proposition or propositions derived by inference. A relevance theoretic account would approach this process in terms of the conventionalization of an inferential routine or process.

If procedural meaning develops from existing conceptual resources, then it would not be surprising for an expression to encode both a concept and a procedure. Although it has been argued that this possibility has been ruled out in relevance theory, it is consistent with relevance theoretic assumptions, and there have been relevance theoretic analyses (e.g., Blakemore's 1987 analysis of *but*, Nicolle's 1997 and 1998 account of *be going to*, and Wilson's 2004 analysis of expressions such as *few* and *several*) where it is argued that a single form may encode two types of meaning.

The Conceptual–Procedural Distinction and Conventional Implicature

While the notion of procedural encoding was developed as a means of analyzing expressions which encode constraints on the recovery of implicit content – e.g., *therefore*, *so*, *after all* – subsequent investigation suggested that it could be extended to expressions that encode constraints on the recovery of explicit content. Some of these – mood indicators, attitudinal particles – are analyzed as encoding constraints on the inferential processes involved in the recovery of higher-level explicatures. For example, Wilson and Sperber (1993) suggest that the use of *huh* in (3) encourages the hearer to construct the

higher-level explicature in (4) (see also Wilson and Sperber, 1988; Clark, 1993):

(3) Peter's a genius, huh!

(4) The speaker of (3) doesn't think that Peter is a genius.

In this case, the equation between procedural meaning and nontruth conditional meaning is maintained, because higher-level explicatures are not regarded as contributing to truth conditional content. However, it has also been suggested that there are expressions, notably pronouns, which should be analyzed as constraints on the proposition expressed, and thus contribute to truth conditional content.

At the same time, it has been argued (Wilson and Sperber, 1993; Ifantidou-Trouki, 1993; Blakemore, 1990, 1996) that expressions such as sentence adverbials or parentheticals which, although they do not contribute to truth conditional content, must be analyzed as encoding concepts (*see* **Parentheticals**). This means that the procedural–conceptual distinction cannot be coextensive with the distinction that underlies Grice's notion of conventional implicature.

If Carston's (2002) conception of linguistic semantics is right, then the fundamental distinction must be the conceptual–procedural distinction rather than the distinction between truth conditional and nontruth conditional meaning. This means that linguistic semantics must include a means of distinguishing conceptual from procedural meaning. Within relevance theory, attention has been drawn to properties that distinguish expressions that encode procedures from those that encode concepts. First, in contrast with concepts, procedures cannot be brought to consciousness (Wilson and Sperber, 1993: 16). This explains why even native speakers find it difficult to judge whether expressions which encode procedures – e.g., *but* and *however* in English or *dakara* and *sorede* in Japanese – are synonymous without testing their intersubstitutability in all contexts. In contrast, even when the definition of a concept proves controversial, speakers can say whether two expressions encode the same concept without having to test whether they can be substituted for each other in every context. If it is difficult for native speakers to make synonymy judgments, then it is not surprising that the translation of expressions that encode procedures is notoriously difficult, particularly since languages do not necessarily conventionalize the same inferential routines. However, the translation of procedural meaning has yet to be investigated systematically.

Second, while expressions that encode concepts can be semantically complex, expressions that encode procedures cannot combine with other expressions to produce semantically complex expressions. Compare (5) with (6):

(5) In total, absolute confidence, she has been promoted.

(6) Sue likes red wine. *Totally however, Mary drinks beer.

Rouchota (1998) has shown that while expressions that have been analyzed as encoding procedures can combine in some way, they do not combine to form complex discourse markers. Compare (7) with (5):

(7) Sue fell asleep during the lecture. But after all, she had heard it all before.

Procedural Analyses of Discourse Markers

The notion of procedural encoding has been applied to the analysis of a range of nontruth conditional discourse markers in a variety of languages (e.g., Blass, 1990; Itani, 1993; Unger, 1996; Matsui, 2002; Iten, 2000; Blakemore, 2002). However, this work has suggested that the original notion is neither sufficiently fine-grained to capture the differences between closely related but nonintersubstitutable discourse markers (e.g., *but* and *however* or *dakara* and *sorede*), nor sufficiently broad to capture all the ways in which linguistic form can encode information about the inferential computations involved in the interpretation of utterances. As it is defined by Blakemore (1987), procedural encoding is linked to the three cognitive effects defined within relevance theory: contextual implication, strengthening, and elimination. In order to account for the differences between expressions such as *but* and *however*, it has been argued that the notion of procedural encoding must be broadened to include the activation of particular types of contexts. Moreover, it has been suggested that the meanings of some discourse markers (e.g., *well*) may not necessarily be linked to the activation of cognitive effects at all (see Blakemore, 2002).

Future Directions

Procedural encoding has also played a role in the analysis of the role of intonation in interpretation (see Fretheim, 2002; House, 2004). If, as Gussenhoven (2002) has argued, aspects of intonation have become grammaticalized so that certain pitch contours encode arbitrary meanings, then it is plausible that these meanings should be analyzed in terms of

instructions for interpretation. However, Wharton's (2003a, 2000b) work on natural codes suggests it may also be possible to generalize the notion of procedural meaning to accommodate phenomena that are on the borderline of language (e.g., interjections) as well as natural or paralinguistic aspects of intonation (*see* **Interjections**). Research in this area has yet to be developed, but it seems clear that the scope of procedural encoding extends beyond the analysis of the non-truth conditional discourse markers.

Meaning, Sense, and Reference

D J Cunningham, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Attempts to define and/or construct a theoretical account of meaning can be found throughout the arts, sciences, and humanities. Dewey and Bentley (1949: 297) contended that the word 'meaning' is "so confused that it is best never used at all." As our task is to characterize meaning from a semiotic point of view, perhaps we can limit rather than contribute to this confusion.

Consider the following scenarios:

- A college student hears her professor use an unfamiliar word and looks it up in her dictionary
- A pedestrian carrying a white cane approaches a busy intersection, pauses, and then walks into the street, whereupon the traffic yields
- A cat races to the kitchen at the sound of an electric can opener
- A doctor sees a dark area on X-ray photograph of the lung of a patient who has been coughing up blood
- An anthropologist observes that among Nestlik Native Americans, sons have a more familiar relationship with their maternal uncle than with their father
- A bicyclist rides past a dog that suddenly raises its head, arches its neck, and bares its teeth
- A husband notices that his wife has suddenly stopped showing any physical affection toward him
- A high school history teacher asks her students to analyze the St. Crispin's day speech from Shakespeare's Henry V as part of their unit on war in England
- A three-year-old child points to the picture of her absent father and says "Daddy!"
- A concert-goer unexpectedly begins to weep while listening to Barber's 'Adagio for strings'.

Within semiotics, these scenarios are often treated as having something very important in common despite their many obvious differences (context, organism, medium, etc.). In one sense, these scenarios all describe an effort after meaning, of the word, cane, sound, shadow, etc. More broadly, they are all examples of semiosis or sign action. In studying these scenarios, in ascertaining the meaning of the word, cane, sound and so forth, we must ask a series of questions: What is a sign? How are these signs organized? How are these signs related to other signs and sign systems?

Since the topic of meaning is so deeply embedded in language and linguistics in general and semiotics in particular, other entries in this encyclopedia have already implicitly or explicitly dealt with the topic. Here, we will try to particularize the meaning of meaning for semiotics by examining some of the distinctions that have been drawn in past attempts to characterize it.

Meanings of Meaning

In their classic book *Meaning of meaning,* Ogden and Richards (1956: 185–208) compiled a 'representative list' of 16 definitions of the word 'meaning,' and several more can be discerned in their full discussion. Included in their list are the familiar meanings, such as a dictionary entry, the feelings or images aroused, an intention (as in 'I **meant** no harm.'), something of significance (as in 'Religion adds **meaning** to my life.'), and so forth. To sort through these and many other definitions, it will be helpful to review some of the distinctions raised in previous philosophical analyses. Many of these accounts focus on the meaning of words and statements, that is, semantics, and one of our tasks here will be to demonstrate how semiotics enables us to look beyond language signs.

Frege (1892) is usually credited with distinguishing between meaning as sense and meaning as reference. Even in the formal language of mathematics, such a distinction seems fruitful. For example, in the equations $2 + 2 = 4$ and $3 + 1 = 4$, both $2 + 2$ and $3 + 1$ refer to the same object, 4, but in different ways. We can say that $2 + 2$ and $3 + 1$ are the same in that they refer to the object 4, but, of course, they are also different than 4 (as sums) and from each other (as two different sums). They are two expressions or senses of the same thing – there is more information contained in them than in the tautology $4 = 4$. Frege's most famous example is that the expressions 'morning star' and 'evening star' both refer to the same celestial object (the planet Venus), but in a different sense (as seen in the morning before sunrise or in the evening after sunset). Meaning as reference tells us **that** a thing is (That object in the sky there is the planet Venus) while meaning as sense tells us **what** a thing is (If there is a bright star in the sky right after sunset, it is the evening star). Meaning as reference proposes an identity, while meaning as sense proposes interpretation. According to Frege, "By means of a sign, we express [the object's] sense and designate its reference" (1892).

Other related accounts of meaning make a distinction similar to Frege's including Carnap on intension (sense) vs. extension (reference) and J. S. Mill on

connotation (sense) vs. denotation (reference). While there are subtle and sometimes not so subtle differences between these accounts and Frege's and among themselves, it is beyond our purposes here to compare them. We will use the sense/reference distinction to examine semiotic models of meaning.

Meaning and Semiotics

As stated above, the topic of meaning is embedded deeply within semiotics in general and the concept of sign in particular. Here we will briefly describe how the two major founders of semiotics, Saussure and Peirce, have dealt with meaning.

Ferdinand de Saussure and Structuralism

Saussure, it will be remembered, regarded the sign as constituted by a signifier (or sound image in the case of speech) and a signified (a concept or idea). Thus the spoken word *tree* is a language sign made up of a signifier (the 'psychological imprint of the sound') for the mental concept Tree, the signified. Saussure sometimes spoke of the relationship between signifier and signified as signification. Since the signified and signifier are both mental concepts, the sign they constitute has no necessary relationship to a reference. In fact, one of the hallmarks of Saussure's semiology is that the relationship between a sign and its object is arbitrary, established by human social convention. Thus the sign *tree* is a language sign in English solely because it has been adopted by use as such, just as the sign *arbor* has been adopted in use by French-speaking communities. Meaning is, therefore, a mentalistic concept for Saussure, arising not from the links between signs and the real objects to which they refer, but from the interplay between and relationships that arise from the action of signs. In short, meaning arises from the structure of signs.

As a linguist, Saussure naturally emphasized language signs and structures. He defined language as a "system of interdependent terms in which the value of each term results solely from the simultaneous presence of others . . ." (Saussure, 1959: 116). Language signs get their meaning within the structure as a whole, in the relationships between one sign and the others. These relationships are particularly determined by differences. Just as at the phonemic level of a language where some sounds are recognized as different and others are not (e.g., the initial sounds of *tin* and *kin* are regarded as different in English whereas those of *coal* and *call* are not), language signs also get their meaning in terms of recognized differences with other language signs. It is therefore the structure of the whole that determines meaning, not reference to independently existing objects.

It is more than just the structures of a language that determine meaning, however. In addition, a language also includes rules for distinguishing one sign from another and for relating signs to one another. These rules, called syntax, allow us to combine and recombine signs in a potentially indefinite number of ways. Without syntax, a structure of signs is static. With syntax, it is possible to manipulate signs and their structure so that new meanings are brought to light or new possibilities for a structure can be constructed. We can therefore build **possible** structures, meanings that may have no embodiment outside of our semiosis. For example, without a system of signs and syntax to manipulate them, we could not build the possible worlds of the past or the future. The past and the future do not exist in our immediate experience, but we can **construct** the past and future and act upon their meanings in language signs using syntax.

Following Saussure, a number of scholars expanded this notion beyond language signs *per se* to all manner of cultural phenomena. Work in this vein is often called structuralism (see Hawkes, 1977 for a useful summary). Many of these analyses explicitly talk of signs in terms of signifiers and signified organized into a language-like structure and organized as if they embody a grammar. So we have semiotic analyses of the 'language' of gesture, dance, clothing, cars, advertisements, professional wrestling, circus, nearly anything you can imagine. Claude Levi-Strauss (1966) dedicated his career to demonstrating that there are underlying systems of structure and meaning behind such dazzlingly varied and complex social systems as kinship patterns (as in scenario 5 above) and myth. Roland Barthes (1964) took all of culture as his domain as he mapped out systems of connotation and denotation for such objects as cars, food, and clothing. There are many other examples, of course.

One important outcome of these analyses is that once you have uncovered the underlying structure for a particular phenomenon, manipulation of the syntax can create new forms of meaning that may not have emerged already; for example, structuralist analyses of advertisements can lead to a reversal or even a mocking of the dominant structures. Mystery stories usually keep the reader in the dark about the perpetrator of the crime until the last chapter, but the television detective show Columbo was very popular, in part, because the culprit was revealed at the beginning.

Structuralist models tend to suggest there is a single meaning to a text, a notion attacked forcefully by poststructuralists such as Derrida (1984). The problem arises from the signifier–signified relationship itself. The meaning of a text cannot reside in the

text but only in the signs that represent the text. As such, the signs are only a part of the potential meanings of any text, and alternate relations lead to alternative meanings. To speak of **the** meaning of a text is nonsense; there will be as many meanings as there are contexts, potential structures of signs to interpret it. But these meanings are nonetheless related to the network of relationships mapped out by the sign system in question. The relation, as Eco (1984) showed, is one of inference, where:

> To walk, to make love, to sleep, to refrain from doing something, to give food to someone else, to eat roast beef on Friday – each is either a physical event or the absence of a physical event, or a relation between two or more physical events. However, each becomes an example of good, bad, or neutral behavior **within a given philosophical framework**. (1984: 10, emphasis his)

C. S. Peirce

Charles S. Peirce was originally drawn to the study of signs by his search for a model of meaning valid for scientific inquiry. For Peirce, hypotheses are signs, inferred from the world of experience to give meaning to aspects of that world. Imagine, for example, stumbling across some bit of experience that, in itself, is quite puzzling and surprising (e.g., scenario 7 above). Yet, if that bit of experience is treated not for its unique properties, but as an example or case or sign of some rule of experience in action (e.g., perhaps the medication she is taking for high blood pressure is reducing her libido), then it is transformed into an ordinary affair. Couple this notion with Peirce's assumption that the things of the world of experience that we claim to be true are at best only more or less plausible and therefore only meaningful hypotheses, and we can begin to understand why the concept of meaning plays such a central role in his theory, why he came to equate logic and semiotics. That signs can be both the product of and further source of inference opens semiotic inquiry in quite a different direction from the structuralist approaches described earlier, to the processes of sign use within organisms: semiosis.

A sign, according to Peirce is "something which stands to somebody for something in some respect or capacity" (2.228 – As is common in Peircean scholarship, quotes and citations will be identified by volume and paragraph number from Peirce [1931–1958]). The sign stands for something, the object, by linking it to an interpretant, an additional sign that stands for some aspect of the object. All three elements, sign, object, and interpretant, are necessary for sign process to occur and are not decomposable into dyads. Thus, Peirce's conception of the sign includes both its sense and its reference, but not as separate components. A sign is only an incomplete representation of the object or referent. Only certain aspects of the object are represented, and it is these aspects that come to define the interpretant, the sense of the sign process. Different signs may represent different aspects of the object and thereby produce different senses. Additionally, signs have aspects that are not relevant to the object (that may be characteristics of the sign as something in the world of experience, but not of the object) and that can produce additional, different interpretants. In other words, our experience of the world is mediated through signs and can never, therefore, be isomorphic with the objects of the world. In essence, we create our world of experience by creating and using signs as we interact with objects in our environment.

Meaning emerges in the action of signs, also called semiosis. The varieties of meaning that are possible are due, in large part, to the complex interplay of sign, object, and interpretant. This interplay is seen clearly in Peirce's sophisticated analysis of signs and sign process. Perhaps his most famous derivation (2.254–2.264) was to propose three trichotomies of signs (or aspects of signs). In brief, these are (1) the nature of the sign itself, (2) its relation to the object it represents, and (3) its relation to the effect it produces (i.e., to its interpretant). In the first trichotomy, the sign itself can be a quality, a single individual thing, or a general type. Peirce labeled these three sign aspects as qualisign, sinsign and legisign, respectively. The second trichotomy is perhaps the best known. A sign can represent an object by resembling it (icon), by being existentially connected to it (index), or by a general rule (symbol). The third trichotomy considers the manner in which the sign relates to its interpretant. The sign can lead to the effect of possibility (rheme), of actual fact or existence (dicent), or of formal law (argument). These trichotomies can be combined to identify additional aspects of sign process. For reasons too complicated to go into detail here, when the three trichotomies outlined above are combined, 10 classes of signs can be identified: Rhematic Iconic Qualisign, Rhematic Iconic Sinsign, Rhematic Iconic Legisign, Rhematic Indexical Sinsign, Rhematic Indexical Legisign, Rhematic Symbolic Legisign, Dicent Indexical Sinsign, Dicent Indexical Legisign, Dicent Symbolic Legisign, and Argument Symbolic Legisign. But the potential varieties of signs do not end here. Peirce estimated that many thousands of sign types could be identified (8.343) but left their identification to 'future explorers.'

What is important to note for our purposes of understanding Peirce's concept of meaning is that the distinctions raised by sign types only identify **aspects** of signs, not isolated pure categories. These

aspects emerge in the action of signs or semiosis, that is, in the quest for meaning. In the perpetual action of semiosis, only certain emphases can be noted, only certain tendencies about the force of the sign action can be identified as the process of semiosis spreads from sign to sign. Sign action is in no way limited to any single triad but spreads throughout a network of interpretants, a process characterized by Eco (1984) as unlimited semiosis. A second point is a derivative of the first. Semiosis is the action of signs, not of a person. Certainly a person is an essential element in any human semiosis, but the action involves all three elements: the sign, object, and its effect. The interpretant **could** be an action, feeling, or thought of a person (Houser, 1987), but in its most general sense, the interpretant could be **any** effect, including additional sign action – a new triad of sign, object, and interpretant. Alternatively, a new aspect of sign process could emerge in a particular context, as when, for example, the iconic aspect of a symbol (e.g., the shape of a word heretofore treated as a symbol) comes to the foreground. For Peirce, meaning is the "proper significate effect of a sign" (5.475).

Consider the following example. Suppose our student in scenario 1 above is looking up the word *ocelot* that she heard her professor use in her Biology class. In her trusty Merriam-Webster, she finds 'one of a family (*Felidae*) of feral, carnivorous, usually solitary and nocturnal mammals.' Not knowing the meaning of *Felidae*, she looks up the word to discover that the ocelot is a variety of cat. This discovery immediately links her to all of the prior knowledge, prior semiosic structures that she constructed from her experiences (feelings, thoughts, and actions) with cats. Returning to the original definition, she looks up other words she does not understand. Under *carnivorous*, she reads 'subsisting or feeding on animal tissue; rapacious.' Never having come across the word *rapacious* before, she looks it up to read 'excessively grasping or covetous; ravenous or voracious.' As she moves from word to word, from interpretant to interpretant, new meanings are attached to her original one. She is slowly developing her structure for ocelot. We can also move beyond words. Our dictionary could include a drawing of an ocelot. Her professor could mime the actions of an ocelot in stalking, crouching, and springing upon its prey. The growl could be recorded and played in the class.

It is in this spread of signs, in the potential for unlimited semiosis, that meaning is to be found. According to Peirce, "a sign is not a sign unless it translates itself into another sign in which it is more fully developed" (5.594). Interpretants become signs for additional semiosis, generating additional interpretants that link to additional objects that in turn become signs for additional semiosis. Of course, this spread does not continue indefinitely. Eventually, it must resolve itself into a set of structures with which the world as we experience it is meaningful to us. Peirce referred to this set of structures as 'beliefs.'

The concept of belief is key in Peirce's view, and he spoke of a semiosis in general and meaning is particular as a movement toward 'fixing' a belief. The converse of belief is doubt, and Peirce was very explicit in drawing the distinction between them:

> We generally know when we wish to ask a question and when we wish to pronounce a judgment, for there is a dissimilarity between the sensation of doubting and that of believing. But this is not all that distinguishes doubt from belief. There is a practical difference. Our beliefs guide our desires and shape our actions . . . Doubt is an uneasy and dissatisfied state from which we struggle to free ourselves and pass into the state of belief; while (belief) is a calm and satisfactory state which we do not wish to avoid, or to change to a belief in anything else. On the contrary, we cling tenaciously, not merely to believing, but to believing just what we do believe. (5.370–5.372)

Peirce called such doubt 'genuine doubt.' As such, it is situated in our experience, not a methodological strategy as in Descartes' use of doubt. Doubt arises when the structures we have created, our current beliefs, do not account for some experience, when the character of signs does not fit our understanding. Peirce proposed four methods of resolving doubt and fixing beliefs: tenacity, authority, *a priori*, and experiment. Briefly, tenacity is invoked whenever one holds on to beliefs in the face of doubt and asserts that the beliefs will eventually accommodate the doubtful event. We use the method of authority to fix beliefs when we accept the beliefs of authority figures like teachers or scientists. Nowhere is the method of authority more widely used, and abused, than in the field of education. The *a priori* method is invoked when our beliefs change in the context of already existing structure of beliefs, a conceptual coherence to a worldview that has served us well so far. The three methods described so far all resolve doubt by opinion, stubbornly maintained, taken from others, or reasoned from premises. The fourth method, which Peirce preferred, is the method of experiment, where one seeks to remove doubt by collecting observations, generating potential hypotheses to account for the surprising experience, and reaching a conclusion based upon the interplay of inferential processes.

Inference, in fact, is implicated in all the methods of resolving doubt. Elsewhere (e.g., 5.145) Peirce describes three modes of inference – abduction, induction, and deduction – through which observers can build and work with structures of signs:

> Deduction is the only necessary reasoning. It is the reasoning of mathematics. It starts from a hypothesis, the truth or falsity of which has nothing to do with the reasoning; and of course its conclusions are equally ideal. The ordinary use of the doctrine of chances is necessary reasoning, although it is reasoning concerning probabilities. Induction is the experimental testing of a theory. The justification of it is that, although the conclusion at any stage of the investigation may be more or less erroneous, yet the further application of the same method must correct the error. The only thing that induction accomplishes is to determine the value of a quantity. It sets out with a theory and measures the degree of concordance of that theory with fact. It can never originate any idea whatsoever. No more can deduction. All the ideas of science come to it by way of Abduction. Abduction consists in studying facts and devising a theory to explain them. Its only justification is that if we are ever to understand things at all, it must be in that way. (5.145)

In the case of the method of experiment, a surprising experience might lead us to abduce a new hypothesis and examine it deductively to see if it squares with the available facts. Suppose, for example, I held the view that individual members of a species tended to be larger in colder climates. Recent data, however, have shown that this difference was not true of fish. If I engage in abduction, I might generate the hypothesis that the original relationship applies only to mammals. If observation showed this hypothesis to be tenable, then the surprising experience would be a matter of course. Deductively, I could link my hypothesis to other varieties of animals and inductively test the consequences. Similar inferential strategies can be observed in *a priori*, authority, and even tenacity.

The validity of our beliefs is tested in accord with Peirce's pragmatic maxim:

> Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object. (5.402)

If our beliefs are adequate to account for the phenomena before us, then we are satisfied. It is doubt that drives semiosis.

One important source of doubt comes from comparing our beliefs with others. Logic is grounded in the collective nature of semiosis itself and oriented toward future activity. Peirce's understanding of community was in terms of both the present communities of practice (scientist, citizen, family member, etc.), and the 'family' of all participants, past and future as well as present, who have, are and will work on clarifying our ideas and understandings.

> Finally, as what anything really is, is what it may finally come to be known to be in the ideal state of complete information, so that reality depends on the ultimate decision of the community; so thought is what it is, only by virtue of its addressing a future thought that is in its value as thought identical with it, though more developed. In this way, the existence of thought now depends on what is to be hereafter; so that it has only a potential existence, dependent on the future thought of the community. (5.316)

In summary, Peirce argued that the subject matter of semiotics is semiosis, the action of signs in all domains of life. Semiosis is an effort after meaning. Our understanding of the world is entirely mediated by signs, and therefore to understand meaning, we must understand the nature of our signs: What is a sign? How is one sign related to another sign? What do signs reveal about the real world? What do they obscure? How are signs formed? What are the ways in which signs can stand for something else? The identification, understanding, and use of signs are fundamental parts of inquiry. In fact, the process of semiotics within inquiry was seen by Peirce to be an emergent process, and one quite explicitly linked to our cognitive natures:

> Symbols grow. They come into being by development out of other signs ... We think only in signs. These mental signs are of mixed nature; the symbol-parts of them are called concepts. If a man makes a new symbol, it is by thoughts involving concepts. So it is only out of symbols that new symbols can grow. *Omne symbolum de symbolo*. A symbol, once in being, spreads among the people. In use and in experience, its meaning grows. Such words as force, law, wealth, marriage, bear for us very different meanings from those they bore for our barbarous ancestors. (2.302)

Dictionary vs. Encyclopedia

In a seminal chapter in his *Semiotics and the philosophy of language*, Umberto Eco (1984: 46–86) further elaborated some of the issues raised above. In particular, Eco explored the question of whether the meaning of a linguistic expression could be captured in a synonymous expression or definition. As in scenario 1 above, the act of consulting a dictionary is often associated with seeking the meaning of a word or phrase. Even in the case of a nonlinguistic sign (as in the white cane of scenario 2, we often convert to linguistic sign (e.g., a *blind* man) and consult a dictionary.

We expect a dictionary to help us pinpoint meaning and disambiguate the meaning of one word from another. For example, the dictionary entry for *ram* should provide a synonymous expression or paraphrase (e.g., *adult male sheep*) as well as

similarities/differences from other words (e.g., *buck, stag, ewe, lamb, wether*). This effect is accomplished by implicit (or sometimes explicit) reference to a hierarchical structure or Porphyrian tree. The synonymous terms or definitions are usually more general or abstract entries arrayed in a tree-like structure that depicts the relationships between the word whose meaning is sought and a network of related ones. For example, to define a ram as an adult male sheep specifies a relationship between ram and sheep but also raises the issues of the definition of sheep, differences between sheep and goats, cows, horses, and so on. Such taxonomies and classifications as this one are common within scientific domains, but the question raised by Eco (1984) is whether these structures actually analyze meaning. Structures achieve their classificatory power by proposing a finite number of hierarchically ordered categories by means of which terms are located. Ram has its place in this structure, and its place is linked to higher order terms (*sheep*, *mammal*, *animal*, *living thing*) and differentiated from other terms (*goats*, *fish*, *plants*, *nonliving*) by its position in the hierarchy. In Frege's terms, such classifications seek to pinpoint the reference where the meaning of a term consists of an analysis that identifies the more abstract referents or properties to which the term in question is related. Ideally, this process should be an automatic one in which there is no ambiguity about whether the classification is correct. Indeed, a computer programmed with the requisite structures could perform our meaning analysis. In such an analysis, there is no room for interpretation!

In a brilliant series of critiques, Eco clearly demonstrated the inadequacy of the 'dictionary' approach to meaning. There is something very artificial about the terms in these hierarchical tree structures – in the languages they use and the worlds they propose. Even at a formal level, logical inconsistencies crop up in even the most 'natural' classification systems. Thus, while a ram is an adult male sheep, it is difficult to construct a classification that appropriately differentiates on all three criteria at once (e.g., is gender superordinate or subordinate to sheep?). The very notion of hierarchy seems very slippery when probed – wool can be a property of and therefore subordinate to sheep in one analysis, whereas sheep can be an instance of and hence subordinate to the category of 'wool-producing animals' in another. Most serious, however, is that the attempt to minimize interpretation ultimately fails. According to Eco (1984: 57), "either the primitives (more abstract referents) cannot be interpreted, and one cannot explain the meaning of a term, or they can and must be interpreted and one cannot limit their number."

Any act of meaning, therefore, must involve both reference **and** sense. To understand the meaning of *ram*, we must inevitably bring to bear some portion of an immense body of potentially relevant world knowledge. In most everyday uses of the word *ram*, for example, connections to generic spheres of knowledge such as animal husbandry, Greek culture, hunting, clothing manufacture, astronomy, climate, etc. are possible as are more personal connections such as living on a sheep ranch, hearing nursery stories about sheep, etc. Most actual dictionaries actually make explicit links to portions of this world knowledge and for this reason, Eco regards them as 'disguised' encyclopedias. In some very specific context, the meaning of the word *water* might be limited to the expression H_2O, but in most contexts, it would be immediately connected to possible spheres of world knowledge related to drinking, washing, sailing, extinguishing fires, and so forth. The task of a person trying to figure out the meaning of a term is, therefore, not one of establishing the referent, but contextualizing the sense in which the referent is being interpreted – in Peirce's terms by means of interpretants in a (potentially unlimited) process of semiosis.

Eco (1984) explored several metaphors to describe encyclopedic competence and settles upon the rhizome. A rhizome is a root crop, a prostrate or underground system of stems, roots, and fibers whose fruits are tubers, bulbs, and leaves. A tulip is a rhizome as is rice grass, even the familiar crab grass. The metaphor of rhizome specifically rejects the inevitability of such notions as hierarchy, order, node, kernel, or structure. The tangle of roots and tubers characteristic of rhizomes is meant to suggest a form of mind where:

- Every point can and must be connected with every other point, raising the possibility of an infinite juxtaposition
- There are no fixed points or positions, only connections (relationships)
- The structure is dynamic, constantly changing, such that if a portion of the rhizome is broken off at any point it could be reconnected at another point, leaving the original potential for juxtaposition in place
- There is no hierarchy or genealogy contained as where some points are inevitably superordinate or prior to others
- The rhizome whole has no outside or inside, but is rather an open network that can be connected with something else in all of its dimensions.

The notion of a rhizome is a difficult one to imagine, and any attempt to view it as a static picture risks minimizing its dynamic, temporal, and even

self-contradictory character. Eco (1984) labeled the rhizome as 'an inconceivable globality' to highlight the impossibility of any global, overall description of the network. Since no one (user, scientist, or philosopher) can describe the whole, we are left with 'local' descriptions, a vision of one or a few of the many potential structures derivable from the rhizome. Every local description of the network is an hypothesis, an abduction, constantly subject to falsification. To quote Eco:

> Such a notion ... does not deny the existence of structured knowledge; it only suggests that such a knowledge cannot be recognized and organized as a global system; it provides only 'local' and transitory systems of knowledge which can be contradicted by alternative and equally 'local' cultural organizations; every attempt to recognize these local organizations as unique and 'global' – ignoring their partiality – produces an **ideological** bias. (1984: 84, emphasis his)

This last statement emphasizes the point that we are not proposing the metaphor of rhizome for an individual mind making meaning, but to **minds** as distributed in social, cultural, historical, and institutional contexts. Except as a degenerate case, there is no such thing as a single mind, unconnected to other minds or to their (collective) social cultural constructions. Thinking, or whatever we choose to call the activity of mind as it makes meaning, is always dialogic, connected to another; either directly as in some communicative action or indirectly via some from of semiotic mediation – signs and/or tools appropriated from the sociocultural context. We are connected to other people individually but also collectively as in the speech communities or social languages in which we are all embedded. We are connected to the sociocultural milieu in which we operate, a milieu characterized by the tools (computers, cars, television, and so forth) and signs (language, mathematics, drawing, etc.) that we may appropriate for our thinking. Thus meaning is not an action that takes place within a mind within a body, but rather at the connections, in the interactions. But, it is worth saying again that this thinking is always 'local,' always a limited subset of the potential (unlimited) rhizomous connections that embody our meanings. Thinking is, rather, a matter of constructing and navigating a local, situated path through a rhizomous labyrinth, a process of dialogue and negotiation with and within a local sociocultural context. Although this analogy fails if pushed too far, the connectivity we have in mind is a bit like the World Wide Web. While the 'results' of a connection to WWW are experienced via an interface with one's local workstation, that experience is possible only as a result of connections with many (potentially an infinite) number of servers all over the world. The local workstation both contributes to (constructs) and is constructed by its connections. Meaning is in the connections.

Umwelt – Meaning beyond Words

Jacob von Uexküll's (1957, 1982) notion of 'Umwelt' reinforces this conception of meaning as arising out of 'local' connections, but also extends the analysis beyond language signs. In his paper titled 'The theory of meaning' (1982; originally published in 1940) von Uexküll elaborated Umwelt as the phenomenal or personal world of an organism; that is, the set of connections constructed by the organism via species-specific sensory characteristics and particular experiences in the physical world. Ticks, for example, individually and collectively, construct their Umwelt in part from their biologically determined sensitivity to butyric acid and the particular physical surroundings in which they find themselves. The tick will climb up a tree or tall grass and launch itself toward a source of butyric acid, usually a passing mammal, burrow into its skin, gorge itself with blood, drop off, lay eggs, and die. The Umwelt of the tick is not its environment, that which an observer of an organism might describe as pre-adjacent to and independent of the organism, but is, rather, that environment as selectively reconstituted and structured according to the particular species' characteristics and according to the specific needs and experiences of the individual organism. The organism and its Umwelt are indivisible – it makes no sense to speak of an organism apart from its personal world. So in this sense, all semiosis is simultaneously distributed and situated in the personal world of an individual organism. From the point of view of its inhabitants, an Umwelt is the actual world of experience; that is, an organism's particular slice of the rhizome is the 'real' world for that organism. As external observers of species and individual organisms, we can attempt to gain some understanding of these worlds, and how they influence and are influenced by the multitude of other worlds to which they are coupled.

In a delightful paper titled 'A stroll through the worlds of animals and men' (1957; originally published in 1934), von Uexküll described numerous examples of the Umwelten that organisms individually and collectively create that then serve to mediate their experience in the world. Bees, dogs, snails, flies, earthworms, and even human children and adults are among the subjects whose Umwelt he attempts to map. Of course, as von Uexküll acknowledged, analyses of an Umwelt will always be partial and incomplete in that we can not fully know the Umwelt, the

systems of meaning, of another. Indeed the same physical object often provides a quite different experience both across and within species. In a famous example, von Uexküll (1957) described the various Umwelten created by a large oak tree: a rough textured and convoluted terrain for a bug, a menacing form for a young child, a set of limbs for a nesting bird, a crop to be harvested by a woodsman, and so on. In all these cases, the environment of the tree was the same; that is, the bark, the height, the limbs were 'available' to each of the organisms, yet their experience of them, their meaning, was quite different. Objects of the world are 'meaning carriers' and our sensory-motor mechanisms are 'meaning receivers.' The coordination of meaning carriers and meaning receivers constitute a 'functional circle' out of which our Umwelt arises. Thus the fundamentals of the meaning making process are shared by all organisms.

However, the human Umwelt, dubbed the 'Lebenswelt' by von Uexküll (1957), includes not only biological and physical factors but cultural ones as well. Although both humans and animals engage in sign action, humans are unique in their ability to consciously manipulate signs, thus enabling them to construct worlds apart from nature and direct experience. The possibility for signs that are arbitrary (e.g., language signs) allows humans individually and collectively to create an infinite array of meanings and possibilities for reality through the manipulation of signs. The importance of signs in creating the Lebenswelt lies in their creative power for infinite representation and meaning-making, or unlimited semiosis as described above. Indeed, culture itself can be described as a web of signs. Culture, in this view, is not some mind-independent, pre-adjacent social reality, but rather a collective construction that is reconstructed (or more accurately co-constructed in context) by each new participant. And via these structures, we literally construct our knowledge dynamically as we interact in the world.

As an example, consider the following. In their provocative book *Metaphors we live by*, Lakoff and Johnson (1980) built a solid case that the way in which we perceive and think about a situation is a function of the metaphors (they could have as easily said sign structures) we have adopted for and use in that situation. If we take a cultural phenomenon like schooling, we can examine the dominant metaphors that define its meaning. Marshall (1988) has argued convincingly that the fundamental metaphor in many schools is 'School Is Work.' We speak of students needing to work harder on their studies, to complete their homework, to earn a grade, and so forth. Teachers are trained to manage their classes and are often held accountable in terms of their productivity. Teachers to whom this metaphor is pointed out often deny it and yet are surprised at how often they catch themselves and other educators using language consistent with the workplace metaphor.

Other metaphors are equally powerful. The notion that the 'Mind Is A Container' is very pervasive and in fact underlies much of our teacher training and instructional design and development. If the mind is a container and knowledge is an entity that can be transferred to the mind (a Conduit metaphor) to fill the void, then naturally the task of the educational system is to facilitate this process of knowledge communication. If, however, we understand the metaphorical basis of our thinking, we can raise the possibility of choosing different metaphors and thereby different meanings, and consequently different roles for educators. If we adopt the metaphor of 'School As A Community Resource,' for example, perhaps we will have our students working on authentic tasks that meet community needs (designing bicycle routes through the city; looking into water quality of local streams, etc.) through which they learn the academic content and skills deemed worthwhile. The focus now becomes not on what the students know, but the processes whereby something can become known, how we know it, and for what purpose.

So all cognition, all human process, is situated in the sense that we as meaning makers are inseparable from our Lebenswelt. Yet as human observers using signs in ways unique to our species, we can gain some awareness of the sign process itself in ourselves and in others and some limited ability to manipulate it. With the recognition that our personal world is some portion of, some selection from, infinite possibilities comes the realization that any attempt to assert our view as global inevitably introduces an ideological bias that must be justified. As we build and rebuild our Lebenswelt, we can gain some reflexive self-identity, some autonomy in determining through deliberate choice what ideological bias we will adopt in our actions and our words. In the felicitous phrase of Peirce, we become 'masters of our own meaning' (5.393). To do so, we must solve the problem of 'other minds.' We structure our interactions in the world in terms of our ideas of how **our** mind works and how **other** minds work. In other words, we are continually engaged in Umwelt research. To understand the meanings of others, we must endeavor to understand our own meanings and how they are connected. The character of any human interaction – but communication in particular – is guided by how the participants establish intersubjectivity based upon their respective conceptions of Umwelt. At its most fundamental level, communication depends upon this intersubjectivity, the raising of a distinction between one's mind

and that of others, all the while attending to their connection.

Summary

We began with the assertion that the topic of meaning is embedded deeply within semiotics in general and the concept of sign in particular. Using Frege's distinction between sense and reference as an analytical tool, we have seen how various models of semiotics have dealt with meaning. From the dazzling array of structuralist accounts of the interplay of meanings in cultural contexts by Saussure and his followers, through Peirce's brilliant integration of both sense and reference in his triadic model of sign and sign process, to the elaborations of Eco and von Uexküll of unlimited semiosis and Umwelt, we can confirm that the whole of semiosis can be seen in large part as an effort after meaning. Meaning is not a possession of an individual or a property inherent in an object, but the inevitable outcome of semiosis, the action of signs.

Returning briefly to the scenarios with which we began this entry, we have seen that even in the prototypical case of looking up the meaning of a word in a dictionary (scenario 1), one is quickly immersed in a rhizomous network of related meanings and experiences. A white cane in the hands of a pedestrian (scenario 2) can have a powerful influence on the behavior of others and in a very real sense comes to define that person in that context. Yet a whole other set of connections, different senses of the person, emerge when our pedestrian sets her cane aside and now uses her hands to drink coffee at a sidewalk cafe. These various senses must be shared by the community if they are to be acted upon. Meaning therefore is always an interactive outcome, not an inherent characteristic of either individuals or objects.

Learning certainly plays a major role in the development of meaning. The cat in scenario 3 learned over time that the sound of the can opener heralded a possible meal. Our doctor in scenario 4 must likewise learn to distinguish between suspicious and ordinary features of an X-ray in order to make a correct diagnosis. Signs do not speak for themselves, they must be interpreted! And in that interpretation, particular conceptual contexts will be brought to bear that highlight some aspects of the complex situation and obscure others. Our anthropologist might be using a structuralist model of culture (e.g., Levi-Strauss) in interpreting scenario 5, a model that stresses certain interpersonal characteristics of this culture while ignoring others. We must always be alert to the fact that meanings can change as interpretive context changes.

Meanings must be communicated if they are to make a difference. The bicyclist and the dog in scenario 6 are, in a sense, searching for a means to coordinate their behaviors, as are the husband and wife in scenario 7. This process of interpretation and coordination draws heavily upon inference, particularly abductive inference. What meaning could account for these unexpected signs that would make them sensible? Generating and testing potential meanings lies at the heart of human semiosis.

Finally, to become 'masters of our own meaning,' we must become more reflexive about the centrality of meaning in our life and how we can play a role in enriching that process. For a child to make the link between a photograph and her absent father (scenario 9) is an achievement that every parent should celebrate, because this act signifies the beginning of an awareness of the difference between a sign and its sense (interpretant) and reference (object). These humble beginnings can grow into the wonders of the hermeneutic process whereby we can come to know the worlds we have created and our role within them. In such worlds, Shakespeare and 'Adagio for strings' become possible. What other wonders await us?

Meaning: Cognitive Dependency of Lexical Meaning

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

It is often thought or implicitly assumed, even in circles of professional semanticists, that predicate meanings, as codified in their satisfaction conditions (*see* **Lexical Conditions**), are lexically fixed in such a way that they automatically produce truth or falsity when applied to appropriate reference objects. This assumption is unfounded. In many, perhaps most, cases, the satisfaction conditions imply an appeal to nonlinguistic knowledge, so that the truth and falsity of assertive utterances are not the product of mere linguistic compositional computation, but are code-determined by nonlinguistic knowledge, either of a general encyclopedic or of a context-bound, situational nature.

An obvious case is provided by a large class of gradable adjectival predicates, such as *expensive*, *old*, and *large*, whose applicability depends on (preferably socially recognized) standards of cost, age, and size, respectively, for the objects denoted by their subject terms. The description of such standards is not part of the description of the language concerned, but of (socially shared) knowledge.

Further obvious examples are 'possession' predicates, such as English *have*, *lack*, and *with(out)*, and whatever lexical specification is needed for genitives, datives, and possessive pronouns. These clearly require general encyclopedic knowledge for their proper interpretation. Consider the following examples:

(1a) This hotel room has a bathroom.
(1b) This student has a supervisor.

For (1a) to be true, it is necessary that there be one unique bathroom directly connected with the room in question, whose use is reserved for the occupants of that room. When the room carries a notice that its bathroom is at the end of the corridor to the right, while the same bathroom serves all the other rooms in the corridor, (1a) is false – not just misleading but false, as any judge presiding over a court case brought by a dissatisfied customer will agree. But for (1b) to be true, no such uniqueness relation is required, as one supervisor may have many students to look after. This is not a question of knowing English, but of knowing about the world as it happens to be.

The same goes for the parallel sentences:

(2a) This is a hotel room with a bathroom.
(2b) This is a student with a supervisor.

Possession predicates, therefore, must be specified in the lexicon as involving an appeal to what is normally the case regarding their term referents. They express a well-known relation of appurtenance between the kind of object referred to in subject position and the kind of object referred to in object position. The semantic description (satisfaction conditions) of *have* and other possessive predicates is thus taken to contain a parameter for 'what is well-known,' making the interpretation of this predicate in each token occurrence truth-conditionally dependent on world knowledge.

Not all possession predicates are subject to the same conditions. Possessive pronouns, for example, may express a relation of 'being responsible for' or 'taking care of,' which other possession predicates cannot express. An example is sentence (3) uttered by a gardener with regard to the flower beds he is tending:

(3) Please don't mess up my flower beds.

This sentence can be uttered appropriately without the speaker implying that the flower beds are owned by him.

Many such examples can be given. Consider the predicate *flat* said of a road, a tire, a mountain, a face, or the world. There is an overall element 'spread out, preferably horizontally, without too much in the way of protrusions or elevations,' but that in itself is insufficient to determine what 'being flat' amounts to in these cases. The full meaning comes across only if it is known what roads, tires, mountains, faces, and the world are normally thought to be like. Dictionaries,

It is often thought or implicitly assumed, even in circles of professional semanticists, that predicate meanings, as codified in their satisfaction conditions (*see* **Lexical Conditions**), are lexically fixed in such a way that they automatically produce truth or falsity when applied to appropriate reference objects. This assumption is unfounded. In many, perhaps most, cases, the satisfaction conditions imply an appeal to nonlinguistic knowledge, so that the truth and falsity of assertive utterances are not the product of mere linguistic compositional computation, but are code-determined by nonlinguistic knowledge, either of a general encyclopedic or of a context-bound, situational nature.

An obvious case is provided by a large class of gradable adjectival predicates, such as *expensive*, *old*, and *large*, whose applicability depends on (preferably socially recognized) standards of cost, age, and size, respectively, for the objects denoted by their subject terms. The description of such standards is not part of the description of the language concerned, but of (socially shared) knowledge.

Further obvious examples are 'possession' predicates, such as English *have*, *lack*, and *with(out)*, and whatever lexical specification is needed for genitives, datives, and possessive pronouns. These clearly require general encyclopedic knowledge for their proper interpretation. Consider the following examples:

(1a) This hotel room has a bathroom.
(1b) This student has a supervisor.

For (1a) to be true, it is necessary that there be one unique bathroom directly connected with the room in question, whose use is reserved for the occupants of that room. When the room carries a notice that its bathroom is at the end of the corridor to the right, while the same bathroom serves all the other rooms in the corridor, (1a) is false – not just misleading but false, as any judge presiding over a court case brought by a dissatisfied customer will agree. But for (1b) to be true, no such uniqueness relation is required, as one supervisor may have many students to look after. This is not a question of knowing English, but of knowing about the world as it happens to be.

The same goes for the parallel sentences:

(2a) This is a hotel room with a bathroom.
(2b) This is a student with a supervisor.

Possession predicates, therefore, must be specified in the lexicon as involving an appeal to what is normally the case regarding their term referents. They express a well-known relation of appurtenance between the kind of object referred to in subject position and the kind of object referred to in object position. The semantic description (satisfaction conditions) of *have* and other possessive predicates is thus taken to contain a parameter for 'what is well-known,' making the interpretation of this predicate in each token occurrence truth-conditionally dependent on world knowledge.

Not all possession predicates are subject to the same conditions. Possessive pronouns, for example, may express a relation of 'being responsible for' or 'taking care of,' which other possession predicates cannot express. An example is sentence (3) uttered by a gardener with regard to the flower beds he is tending:

(3) Please don't mess up my flower beds.

This sentence can be uttered appropriately without the speaker implying that the flower beds are owned by him.

Many such examples can be given. Consider the predicate *flat* said of a road, a tire, a mountain, a face, or the world. There is an overall element 'spread out, preferably horizontally, without too much in the way of protrusions or elevations,' but that in itself is insufficient to determine what 'being flat' amounts to in these cases. The full meaning comes across only if it is known what roads, tires, mountains, faces, and the world are normally thought to be like. Dictionaries,

even the best ones, limit themselves to giving examples, hoping that the user will get the hint.

Another example is the predicate *fond of*, as in:

(4a) John is fond of his dog.
(4b) John is fond of cherries.
(4c) John is fond of mice.

In (4a), obviously, John's fondness is of a rather different nature from what is found in (4b): the fondness expressed in the one is clearly incompatible with the fondness expressed in the other. The fondness of (4c) can be either of the kind expressed in (4a) or of the kind expressed in (4b). The common element in the status assigned to the object-term referents is something like 'being the object of one's affection or of one's pleasure,' but again, such a condition is insufficient to determine full interpretation.

Cognitive dependency is an essential aspect in the description of predicate meanings. The fact that some predicate meanings contain a parameter referring to an available nonlinguistic but language-independent, cognitive knowledge base means that neither utterance-token interpretation nor sentence-type meaning is compositional in the accepted sense of being derivable by (model-theoretic) computation from the linguistic elements alone. As regards utterance-token interpretation, this is already widely accepted, owing to valuable work done in pragmatics. The noncompositionality of sentence-type meaning, defined at the level of language description, is likewise beginning to be accepted by theorists of natural language. This type-level noncompositionality does not mean, however, that the specification of the satisfaction conditions of predicates is not truth-conditional, only that standards embodied in socially accepted knowledge have become part of the truth conditions of sentences in which the predicate occurs.

In most treatises on lexicology, the term polysemy is used for phenomena such as those presented above. At the same time, however, it is widely recognized that this is, in fact, little more than a term used to give the problem a name. The problem itself lies in the psychology of concepts. One may assume that there are socially shared concepts like 'possession,' 'flatness,' and 'fondness,' but it is not known in what terms such concepts are to be defined. In a general sense, Fodor (1975, 1998) is probably right in insisting that lexical meanings are direct reflexes of concepts that have their abode in cognition but outside language. The necessary and sufficient conditions taken to define the corresponding lexical meanings cannot, according to Fodor, be formulated in natural language terms, but must be formulated in a 'language of thought,' which is categorically different from any natural language and whose terms and combinatorial properties will have to be established as a result of psychological theorizing.

It is clear, in any case, that phenomena like those shown in (1)–(4) pose a serious threat to any attempt at setting up a model-theoretic theory of lexical meaning, such as Dowty (1979): the neglect of the cognitive factor quickly becomes fatal in lexical semantics.

Context-bound or situational knowledge plays a role in the interpretation of predicates that involve a 'viewpoint' or 'perspective,' such as the pair *come* and *go*, or predicates such as *to the right (left) of*, *in front of*, and *behind*. The two versions of (5) are truth-conditionally identical, but they differ semantically in that the 'mental camera,' so to speak, has stayed in the corridor in the *went* version, but has moved along with Dick into the office in the *came* version.

(5) Dick and Harry were waiting in the corridor. Then Dick was called into the office. After five minutes, Harry [went/came] in too.

In similar manner, the sentences (6a) and (6b) may describe the same situation, but from different points of view. In (6a), schematically speaking, the viewer, the tree, and the statue are in a straight line; in (6b), it is the viewer, the tree, and the fountain that are in a straight line:

(6a) There was a statue behind the tree, and a fountain to the left of the tree.
(6b) There was a fountain behind the tree, and a statue to the right of the tree.

A further cognitive criterion for the lexical meaning of predicates, especially those denoting artifacts, seems to be the function of the objects denoted. What defines a table or a chair is not their physical shape or the material they are made of, but their socially recognized function. The same holds for a concept like 'luxury.' Laws imposing special taxation on luxury goods or luxury activities usually enumerate the goods and activities in question, making exceptions for special cases (such as frock coats for undertakers). Yet what defines luxury is not a list of goods or activities, but socially recognized function – roughly, anything relatively expensive and exceeding the necessities of life.

A peculiar example of cognitive dependency, probably based on function, is provided by the English noun *threshold* and its Standard German translation equivalent *Schwelle*. In their normal uses, they denote the ridge or sill usually found between doorposts at floor level. Yet these two words differ in their capacity for semantic extension: the elevations in roads and streets that are normally called *speed bumps* in

English are called *Schwelle* in German. Yet it is unthinkable that speed bumps should be called *thresholds* in English. The question is: why? One is inclined to think that, at some ill-understood level of interpretation, the word *threshold* implies containment within a space or a transition from one kind of space to another, perhaps as a result of its etymology (which is not fully known). *Schwelle*, by contrast, is a swelling in the ground that forms an obstacle to be got over – which is also its etymology, although, on the whole, German speakers do not realize that. The difference between the two words is not a question of the ontological properties of the objects concerned, but, apparently, of the ways they are conceived of. The role of etymology in this case is intriguing.

How do children assign meanings to words? This task is central to the acquisition of a language: words allow for the expression of the speaker's intentions, they combine to form larger constructions, and the conventional meanings they have license their use for making references in context. Without them, there is no language. In the acquisition of meaning, children must solve the general mapping problem of how to line up word forms with word meanings. The forms are the words they hear from other (mainly adult) speakers. The meanings they must discern in part from consistencies in speaker usage in context from one occasion to the next and in part from inferences licensed by the speaker on each occasion. Possible meanings for unfamiliar words, then, are built up partly from children's conceptual representations of events and partly from the social interactions at the heart of adult-child conversation.

One critical task for children is that of working out the conventional meanings of individual words (e.g., *cup, team, friend, truth*). Yet, doing so is not enough: syntactic constructions also carry meanings that combine with the meanings contributed by the actual words used (causative constructions, as in *They broke the cup* or *The boy made the pony jump*; the locative construction, as in *She put the carving on the shelf*; the resultative construction, as in *He washed the floor clean*). However, children start mapping word meanings before they begin combining words.

Languages differ in how they lexicalize information – how they combine particular elements of meaning into words – and in the kinds of grammatical information that have to be expressed. They may package information about events differently; for example, combining motion and direction in a single word (*depart*) or not (*go + toward*), combining motion and manner (*stroll*), or not (*walk slowly*). They also differ in the grammatical distinctions made in each utterance. Some always indicate whether an activity was completed; others leave that to be inferred. Some always indicate whether the speaker is reporting from direct observation, or, for example, from the report of someone else. Some indicate whether object-properties are inherent or temporary. The grammatical distinctions that languages draw on vary, as do the ways in which they lexicalize information about objects and events. Mapping meanings onto words is not simply a matter of equating meanings with conceptual categories. Children have to select and organize conceptual information as they work out what the conventional meanings are for the words they are learning.

How do children arrive at the meanings they first assign to unfamiliar words? How do they identify their intended referents? And how do they arrive at the relations that link word meanings in different ways? The general conversational context itself serves to identify relevant information on each occasion for children trying to work out the meaning of an unfamiliar word. Adult language use presents them with critical information about how words are used, their conventional meanings, and the connections among words in particular domains.

English are called *Schwelle* in German. Yet it is unthinkable that speed bumps should be called *thresholds* in English. The question is: why? One is inclined to think that, at some ill-understood level of interpretation, the word *threshold* implies containment within a space or a transition from one kind of space to another, perhaps as a result of its etymology (which is not fully known). *Schwelle*, by contrast, is a swelling in the ground that forms an obstacle to be got over – which is also its etymology, although, on the whole, German speakers do not realize that. How do children assign meanings to words? This task is central to the acquisition of a language: words allow for the expression of the speaker's intentions, they combine to form larger constructions, and the conventional meanings they have license their use for making references in context. Without them, there is no language. In the acquisition of meaning, children must solve the general mapping problem of how to line up word forms with word meanings. The forms are the words they hear from other (mainly adult) speakers. The meanings they must discern in part from consistencies in speaker usage in context from one occasion to the next and in part from inferences licensed by the speaker on each occasion. Possible meanings for unfamiliar words, then, are built up partly from children's conceptual representations of events and partly from the social interactions at the heart of adult-child conversation.

One critical task for children is that of working out the conventional meanings of individual words (e.g., *cup, team, friend, truth*). Yet, doing so is not enough: syntactic constructions also carry meanings that combine with the meanings contributed by the actual words used (causative constructions, as in *They broke the cup* or *The boy made the pony jump*; the locative construction, as in *She put the carving on the shelf*; the resultative construction, as in *He washed the floor clean*). However, children start mapping word meanings before they begin combining words.

Languages differ in how they lexicalize information – how they combine particular elements of meaning into words – and in the kinds of grammatical information that have to be expressed. They may package information about events differently; for example, combining motion and direction in a single word (*depart*) or not (*go + toward*), combining motion and manner (*stroll*), or not (*walk slowly*). They also differ in the grammatical distinctions made in each utterance. Some always indicate whether an activity was completed; others leave that to be inferred. Some always indicate whether the speaker is reporting from direct observation, or, for example, from the report of someone else. Some indicate whether object-properties are inherent or temporary. The grammatical distinctions that languages draw on vary, as do the ways in which they lexicalize information about objects and events. Mapping meanings onto words is not simply a matter of equating meanings with conceptual categories. Children have to select and organize conceptual information as they work out what the conventional meanings are for the words they are learning.

How do children arrive at the meanings they first assign to unfamiliar words? How do they identify their intended referents? And how do they arrive at the relations that link word meanings in different ways? The general conversational context itself serves to identify relevant information on each occasion for children trying to work out the meaning of an unfamiliar word. Adult language use presents them with critical information about how words are used, their conventional meanings, and the connections among words in particular domains.

Conventionality and Contrast

Adult speakers observe two general pragmatic principles when they converse. First, they adhere to the conventions of the language they are speaking and in so doing make sure their addressees identify the meanings intended in their utterances. The principle of conventionality takes the following form: 'For certain meanings, there is a form that speakers expect to be used in the language community.' So if there is a conventional term that means what the speaker wishes to convey, that is the term to use. If the speaker fails to use it or uses it in an unusual way, that speaker risks being misunderstood. For conventions to be effective, conventional meanings must be given priority over any nonconventional ones. The second general principle speakers observe is that of contrast: 'Speakers take every difference in form to mark a difference in meaning.' When speakers choose a word, they do so for a reason, so any change in word choice means they are expressing a different meaning.

These two principles work hand-in-hand with the Cooperative principle in conversation and its attendant maxims of quality (be truthful), quantity (be as informative as required), relation (make your contribution relevant), and manner (avoid ambiguity; Grice, 1989). Acting in a cooperative manner demands that one observe the conventions of the language in order to be understood. At the same time, if there is no conventional term available for the meaning to be expressed, speakers can coin one, provided they do so in such a way that the addressee will be able to interpret the coinage as intended (Clark, 1993).

In Conversation

Adults talk to young children from the very start, and what they say is usually tied closely to specific objects and activities. This feature of conversation presents young infants with opportunities to discern different intentions, marked by different utterances from early on. Infants attend to adult intentions and goals as early as 12 months of age. They show this, for example, by tracking adult gaze and adult pointing toward objects (e.g., Carpenter *et al.,* 1998), so if they are also attentive to the routine words and phrases used on each type of occasion, they have a starting point for discerning rational choices among contrasting terms and gestures.

Consider the general conditions for conversational exchange: joint attention, physical co-presence, and conversational co-presence. Adults observe these conditions and indeed impose them, as they talk to very young children. They work to get 1- and 2-year-olds to attend, for instance when planning to tell them about an unfamiliar object, and only then do they talk to them about whatever object or event is visibly present (Clark, 2001). By first establishing joint attention, adults set young children up to identify and then to help add to common ground. Children can do this by ratifying offers of new words by repeating them or else indicating in some other way that they have taken up an unfamiliar term (Clark, 2003).

When adults offer unfamiliar words, they do so in the conversational context; that is, with children who are already attending to whatever is in the locus of joint attention. This feature, along with any familiar terms that are co-present in the conversation, allows children to make a preliminary mapping by identifying the intended referent, whether it is an object or an action (Tomasello, 2002). In effect, the conditions on conversation narrow down the possible meanings that young children might consider for a new term to whatever is in the current joint focus of attention.

However, adults do more in conversation. They accompany their offers of unfamiliar words with additional information about the intended referent on that occasion and about how the target word is related to other terms in the same semantic field. Among the semantic relations adults commonly offer are inclusion (*An X is a kind of Y*), meronomy or partonomy (*An X is part of Y*), possession (*X belongs to Y*), and function (*X is used for Y*; Clark and Wong, 2002). After offering one term, adults often offer others that happen to contrast in that context, so a dimensional term like *tall* may be followed up by *short, wide, narrow*, and *long* (Rogers, 1978). In fact, the meanings of words for unfamiliar actions may also be inferred in part from their co-occurrence with terms for familiar objects affected by those actions, and the meanings of words for unfamiliar objects may be inferred in part from the verbs with which the nouns in question occur (e.g., Goodman *et al.,* 1998; Bowerman, 2005). All this information offers ways for children to link new terms to any relevant words they already know. Children learn from child-directed speech about general properties of the lexicon – taxonomic relations, nonoverlapping categories within levels, opposites, overlaps in meaning (through hierarchical connections) vs. in reference, and so on.

In short, adults are the experts in providing the conventional terms used for specific meanings in the speech community. The novices, children, ask them innumerable *What's that?* questions from around age 2;0–2;6 on and treat them as reliable sources for how to talk about new things (e.g., Diesendruck and

Markson, 2001). Moreover, when young children make errors, adults frequently check up, through side sequences and embedded corrections, on what they intended to say, and so present children with the conventional forms to aim for (Chouinard and Clark, 2003).

Making Inferences

When children hear a new term for some object or activity, they can infer in context that the term probably applies to the object or activity to which they are attending. However, the information that adults often follow up with allows children to make more detailed inferences about the candidate meaning. Mention of class membership – for example, *A sparrow is a bird* – tells them that they can add the term *sparrow* to the set of terms they already know for birds, perhaps just *chicken* and *duck*. Comments on the size, characteristic song, or flight each allow further inferences about how sparrows differ from ducks and chickens.

What evidence is there that young children take in such information? In spontaneous conversations, they give evidence of attending to what adults say in several ways. First, they repeat new terms in their next conversational turn, either as single words or embedded in a larger utterance; second, they acknowledge the adult offer with forms like *yeah, uh-huh*, and *mmh*; and third, they continue to talk about the relevant semantic domain (Clark, 2004).

Children's readiness to make inferences from added information offered by adults has also been examined in word-learning experiments. In one study, children aged just 2 years old were taught words for two sets of objects (A and B) that were similar in appearance and had the same function. After teaching the first word for the first set (A), the experimenter introduced the second set of objects while saying just once, "Bs are a kind of A." He then proceeded to teach the second word, B. Children were then tested by asking them to find all the As and then all the Bs. For the first request, they typically selected As; for the second, they consistently (and correctly) picked only Bs (Clark and Grossman, 1998). In short, the one statement of an inclusion relation was enough for even young 2-year-olds to make use of it in this task. In another condition, again teaching two new words for two sets that resembled each other, children infer that there could be an inclusion relation but they have no way to tell which way it should go, so some include A in B, and some B in A.

Children rely on contrast in context to make inferences about the most probable reference for a newly introduced word. For example, if they already know what the object they are attending to is called, they are more likely to infer that a new term denotes a subordinate, a part, or some other property of it (Taylor and Gelman, 1989). This propensity was exploited directly in studies of whether children could decide in context whether a new word was intended to denote an object or an activity. Young 2-year-olds were presented with the same object doing different actions, with one action labeled with the new term, or else several objects, one labeled with the new term and all doing the same action. The children readily inferred that the new word denoted an activity in the first case and an object in the second (e.g., Tomasello, 2002).

Young children are also able to discern the intended from the accidental. When shown various actions being demonstrated, infants aged 18 months imitated intended actions (marked by utterances like '*There*') more frequently than unintended ones (signaled by utterances like '*Oops*'). By age 2, young children know to ignore errors in wording, for example, and attend only to the final formulation of what someone is saying. In one study, for example, children were taught a word for a set of objects; then the experimenter exclaimed, "Oh, I made a mistake: these aren't As, they're Bs" and proceeded to teach the word B in place of the earlier A. When tested, even children who were just 2 years old knew that they did not know what A, the first word, meant (e.g., Clark and Grossman, 1998).

All the inferences presented so far have been overt inferences about unfamiliar word meanings, made on the spot by children exposed to the new words. Yet, although adults make clear offers of new words, marking them as new by introducing them in formulaic deictic frames (e.g., *This is a* . . .), with utterance-final stress, many of the other words they use will be unfamiliar to very young children. How do children assign meanings to all those words? The answer lies in the covert use of Roger Brown's (1958) "original word game." Basically, the child notices an unfamiliar word, makes inferences in context about its probable meaning and acts on that, and then adjusts those inferences in light of the adult's responses. Consider these scenarios by way of illustration:

(a) Young child watching parent in the kitchen, with several drink containers on the counter
Mother (to older sibling): Hand me that mug, will you?
(Child, wondering what a mug is, watches sibling pick up a mug)
Mother: Thanks
(Child infers for now that *mug* denotes something that has a handle, is a solid color, and is made of ceramic)

Sometimes, the inferences that children make are informed slightly more directly by the parent's direct responses, as in (b).

(b) Young child holding two plastic animals, a cat and a dog
Father: Can you give me the spaniel?
(Child, uncertain what spaniel means, holds out the cat)
Father: No, the spaniel please.
(Child infers that *spaniel* must refer to a kind of dog rather than a kind of cat, and so hands over the plastic dog instead)

In both cases, the child makes preliminary or tentative inferences that can then be adjusted or changed in light of adult follow-up utterances, further exposures in other contexts, and additional, often explicit information about inclusion, parts, properties, or functions. Of course, inferences like these can also be made about terms for actions, relations, and states, as well as about those for objects, parts, and properties.

Pragmatics and Meaning

In the conversational exchanges considered so far, adult and child both follow the cooperative principle characterized by Grice (1989), as seen by their observation of joint attention, physical co-presence, and conversational co-presence. In addition, each participant in the exchange must add to common ground and keep account of the common ground that has been accumulated so far (H. Clark, 1996). All of this requires that speakers keep careful track of the intentions and goals being conveyed within an exchange (Tomasello, 1995; Bloom, 2000).

Infants are attentive to nonlinguistic goals very early. For example, if 14-month-olds are shown an unusual action that achieves a goal – for example, an adult bending down to touch a panel switch with her forehead – they imitate it. If 18-month-olds watch an adult try and fail to place a metal hoop on a prong, the infants will produce the action successfully, even though they have never seen it completed (Meltzoff, 1995). That is, infants infer that the adult intended to turn on the light or intended to hang up the hoop. Intentions are what is critical, Meltzoff demonstrated, not just observation of the relevant actions, because infants do not re-enact these events when the actions are performed by a mechanical hand.

In much the same way, infants attend to the words that adults use. Upon hearing a word, they infer that the speaker is referring to the entity physically present in the locus of joint attention. If instead the speaker produces a different word, they infer that the speaker is now referring to something else and therefore has a different goal in speaking. That is, each linguistic expression chosen indexes a different intention, thus exemplifying the speaker's reliance on contrast, as well as on conventionality (Clark, 1993). This recognition then licenses young children to use words to express their intentions and in this way to convey specific goals. Adult usage provides the model for how to do so within conversational exchanges.

Infants also grasp quite early that the words used to express certain meanings are fixed and conventional. For example, they know that adults who wish to refer to a squirrel use the term 'squirrel' or to refer to a sycamore tree use the term 'sycamore,' and so on. As a result, when they notice adults who fail to use 'squirrel' when looking at a squirrel, but instead use another expression, they can readily infer that the speaker must therefore mean something else. In effect, young children, just like adults, assume that if the speaker intends to talk about a squirrel, he will use the conventional term for it. If instead, he uses something else, then he must intend to convey some other meaning.

As a result, in situations where children already know terms for some of the objects they can see, they expect the adult to use a familiar term for any familiar object. If the adult instead produces an unfamiliar term, in the presence of an unfamiliar object, they will infer that he intended to refer to the object for which they do not yet have a term. So they use contrast, together with the assumption that conventional terms always take priority, to interpret the speaker's intentions on such occasions. The result is that they consistently assign unfamiliar terms to as-yet unnamed objects or actions. This pragmatic strategy for interpreting intentions and thereby making a first assignment of meaning to an unfamiliar word helps young children in many settings. Take the case of an adult looking at a single familiar object that is well known to the child. The adult, clearly talking about that object, does not use the expected conventional term. What can the child infer from that? There are two common options: (1) the unfamiliar expression denotes a superordinate or subordinate category, or (2) it denotes a part or property of the familiar object. Then, the remainder of the utterance can typically provide the child with important clues about the correct inference. For example, production of a familiar term for a known object is typically followed by a part term accompanied by a possessive pronoun (as in *his ear*), whereas such expressions as *is a kind of* or *is a* are associated with assignments to class membership in a superordinate category (Clark and Wong, 2002; Saylor and Sabbagh, 2004). Use of a verb like *looks* or *feels* (as in *it looks smooth, it feels soft*) often accompanies the introduction of property terms, and when the unfamiliar term is introduced before the

familiar one with *kind of* (*a spaniel is a kind of dog*), the child readily infers that the new term, here *spaniel*, designates a subordinate category. Finally, children as young as age 2 rely on a combination of syntax cues and physical co-presence in identifying generic noun phrases; for example, when asked something like *What noise do dogs make?* with just one dog in sight.

What these findings indicate is that even very young children are highly attentive to the locus of joint attention and to whatever is co-present physically and conversationally. When one adds in whatever linguistic knowledge children have already built up about word meanings and constructions, it becomes clear that they have an extensive base from which to make inferences about possible, plausible meanings of unfamiliar words. This holds whether the words are presented explicitly as 'new' by adult speakers or whether children simply flag them *en passant* as unfamiliar and therefore in need of having some meaning assigned.

At the same time, young children may have a much less firm grasp on the meanings of many of their words than adult speakers, and incidental or even irrelevant pragmatic factors may affect their interpretations and responses. Take the case of the Piagetian conservation task where the experimenter 'checks up' on the 5- or 6-year-old near-conserver's answer by asking, for the second time, whether the amount that has just been transferred to a new container or transformed into a different array "is still the same." Children on the verge of conserving typically change their initially correct answers from 'yes' to 'no' at this point. They do so because, pragmatically, asking the same question a second time signals that the initial answer was unsatisfactory (Siegal, 1997).

Another Approach

In another approach to the acquisition of lexical meaning, some researchers have proposed that the task is so complex for young children that they must start out with the help of some *a priori* constraints. These constraints are designed to limit the kinds of meanings children can attribute to new words. What form would these constraints take, and what evidence is there for them?

Among the constraints proposed are whole object – 'Words pick out whole objects' – and mutual exclusivity: 'Each referent is picked by just one word' (e.g., Markman, 1989). The whole object constraint predicts that young children should assume that any unfamiliar word picks out a whole object and not, for example, a part or property of that object. The mutual exclusivity constraint predicts that young children should assume that an unfamiliar word must pick out something other than whatever has a name that is already known to the child. So this constraint predicts that children will systematically reject second terms they hear apparently applied to an already labeled referent, as well as fail to learn second terms.

The predictions from these and other constraints have been tested in a variety of word-learning experiments where the target referents are objects. In fact, the whole object and mutual exclusivity constraints apply only to words for objects, so they would have infants treat all unfamiliar words as if they designated only objects and never actions, relations, or properties. How do such constraints work, as they conflict with many properties of word meanings? For example, mutual exclusivity would cause children to not learn inclusion relations in taxonomies because they would need to apply two or more terms to the same referent category in learning that an X can be called a *dog*, specifically a subtype called a *spaniel*, and that a dog is also a kind of *animal*. The whole object constraint would cause children to not learn terms for parts and properties. It would militate against children learning any terms for activities or relations.

One could propose that such constraints apply only in the early stages of acquisition, after which they are overridden. However, then one has to specify what leads to their being overridden; in other words, what the necessary and sufficient conditions are for each constraint to be dropped so children can start to learn words for activities and relations, say, from adult usage, or words for parts and properties, as well as words for objects. Under this view of meaning acquisition, children could start out observing the various constraints and then drop each one at a certain stage in development so as to be able to learn other kinds of meanings up to then blocked by the constraints. In short, children should at first ignore much of what their parents say about words and word meanings and reject second labels whenever they are offered to mark a different perspective, for example. They should also look for words only to pick out objects, mistakenly assigning any that might, in context, seem to be designating categories of actions or relations as words for objects instead.

Is this a realistic picture of development? No, because it calls for selectively ignoring or rejecting a large amount of what adults do with language as they talk about the world to their children, offer them words for objects and events in the locus of joint attention, and provide extensive commentary on parts, properties, motion, and functions associated with specific category members. The constraints approach ignores conditions imposed on conversational

exchanges, such as joint attention, and physical and conversational co-presence, and what they contribute to assigning meaning. It also conflicts with adult usage, which offers a range of perspectives on specific objects and events. A piece of fruit can be just that, *fruit*, or it can be *an apple, dessert*, or *a snack*, depending on the perspective chosen (Clark, 1997). Yet, these factors must all be taken into account in both designing and interpreting studies of meaning acquisition.

Sources of Meanings

Children draw on conceptual categories already known to them and on information offered in context, both nonlinguistic and linguistic, when they assign a first meaning to new words. Infants build up and organize conceptual categories of the objects, relations, and events they observe months before they try to use words to evoke the relevant categories. As they assign candidate meanings, they rely on these conceptual categories to connect category instances and words as they start in on language (Slobin, 1985). However, because languages differ, children learn, for purposes of talking, to attend automatically to some aspects of events and ignore others; for example, whether an action is complete or not or whether the speaker witnessed an event for herself or simply heard about it. It is therefore important to distinguish between conceptual knowledge about events and the knowledge speakers draw on when they talk about those events (Slobin, 1996).

Children try to make sense of what the adult wants. This means relying on any potentially useful source of information for interpreting and responding to adult utterances. What children know about the conceptual categories that appear to be at the focus of joint attention seems to provide initial strategies for coping when they do not yet understand all the words. The physical and conversational contexts, with joint attention, identify the relevant 'space' in which to act. This holds just as much for responding to half-grasped requests as for direct offers of unfamiliar words. Children attend to what is physically present, to any familiar words, and to any conceptual preferences. These preferences may include choosing greater amounts over lesser ones, assuming that the first event mentioned is the first to occur, and exchanging one state of affairs for another (Clark, 1997). Such coping strategies may be consistent with the conventional meanings of certain words, so children will appear to understand them when in fact they do not. The match of coping strategies and meanings offers one measure of complexity in acquisition: Matches should be simpler to acquire than cases of mismatch.

Children can draw on what they already know about objects and events, relations, and properties for their world so far. Their current knowledge about both conceptual categories and about their language at each stage offers potential meanings, in context, assignable to unfamiliar words. These preliminary meanings can be refined, added to, and reshaped by adult usage on subsequent occasions. This way, children learn more about the meanings that abut each word, the contrasts relevant in particular semantic domains, and the number of terms in a domain that have to be distinguished from one another. To succeed in this effort, children have to identify consistent word uses for specific event-, relation-, and object-types. They have to learn what the conventions are for usage in the speech community where they are growing up (e.g., Eckert, 2003).

Summary

As children learn new words, they rely on what they know so far – the conceptual and linguistic knowledge they have already built up – to assign them some meaning in context. These initial meanings draw equally on their own conceptual categories and on adult patterns of word use within the current conversational exchange. In effect, joint attention, along with what is co-present physically and conversationally, places pragmatic limits on what the meaning of an unfamiliar word is most likely to be. In addition, adults often provide further information about the referent object or action, linking the word just offered to other words for relevant properties and actions, and thereby situating the new word in relation to terms already known to the child. This framing by adults for new word meanings licenses a variety of inferences by the child about what to keep track of as relevant to each particular word meaning (Clark, 2002). Adults here are the experts and constitute both a source and resource for finding out about unfamiliar word meanings.

Meaning: Overview of Philosophical Theories

R M Martin, Dalhousie University, Halifax, NS, Canada

The Direct Reference Theory

It is obvious that an important fact about language is that bits of it are systematically related to things in the world. 'Referential' theories of meaning hold that the meaning of an expression is a matter, somehow, of this connection.

The most immediately plausible application of this theory is to the meaning of proper names: the name 'Benedict Spinoza' is connected to the philosopher, and this fact appears to exhaust the meaning of that name. The other names – 'Benedictus de Spinoza,' 'Baruch Spinoza,' and 'Benedict d'Espinosa' – mean the same because they are connected to the same person.

But even in the case of proper names, problems arise. For example, consider proper names with nonexistent references: 'Santa Claus.' If the meaning of a proper name is constituted by nothing but its relationship to the bearer of that name, then it follows that 'Santa Claus' is meaningless; but this seems wrong, because we know perfectly well what 'Santa Claus' means, and we can use it perfectly well, meaningfully. Another example would be the two proper names applied to the planet Venus by the Ancient Greeks, who were unaware that it was the same planet that appeared sometimes in the evening sky, when they called it 'Hesperus' and sometimes in the morning sky, when they called it 'Phosphorus.' Because these two names in fact refer to one and the same object, we should count them as having exactly the same meaning. It would appear to follow that someone who knew the meaning of both names would recognize that the meaning of one was exactly the same as the meaning of the other, and therefore would be willing to apply them identically. But the Greeks, when seeing Venus in the morning sky, would apply 'Phosphorus' to it, but refuse to apply 'Hesperus.' Does it follow that they did not fully understand the meanings of those terms? That is an implausible conclusion, since these are terms of the ancient Greek language: how could the most competent speakers of that language fail to understand the meanings of two terms in that language? It looks much more plausible to say that the fact that Hesperus and Phosphorus are identical is not a consequence of the meanings of those words. So meaning is apparently not exhausted by reference. (This example and this argument were originated by Frege.)

But here is a second sort of difficulty for the reference theory. Even if it could do a plausible job of explaining the meaning of proper names, it is not at all clear what it should do with other elements of language. Proper names, after all, make up only a small part of language, and an atypical part, insofar as meaning is concerned, at that; one does not find them in most dictionaries, for example.

Consider whether this sort of approach to meaning might be extended to linguistic items other than proper names. It is a short step from there to more complex, less direct ways of referring, for example, 'the Amsterdam-born author of the *Ethics*.' If this definite description gets its meaning by its reference, then since it refers to Spinoza again, it must mean the same as those other names. But a problem immediately arises here, similar to the 'Hesperus/Phosphorus' worry. One might understand the meaning of 'Benedict Spinoza' perfectly, it seems, without knowing some facts about the philosopher, for example, that he was born in Amsterdam and wrote the *Ethics*; and, as a result, although one understood 'the Amsterdam-born author of the *Ethics*' he or she would not know that this referred to Spinoza. A similar problem arises with the 'Santa Claus' worry: 'the present king of France' is surely meaningful, although it is without reference (Russell's famous example).

Still other linguistic elements provide greater difficulty for a reference theory. How, for example, is the meaning of the predicate 'is wise,' occurring, for example, in 'Spinoza is wise,' to be explained in terms of reference? Particular wise objects exist, to be sure – Spinoza for one. But clearly it is not helpful to think that 'is wise' here gets its meaning merely by referring to Spinoza again – which would add nothing – or to some other wise person – which seems irrelevant. And what if that sentence were false (but meaningful), and Spinoza were not among the wise things: what would 'is wise' refer to then? More likely 'is wise' refers to a set of things – the wise individuals (Spinoza, Socrates, Bertrand Russell, etc.). But the sentence clearly tells us more than that Spinoza belongs to the group Spinoza, Socrates, Bertrand Russell, etc. It refers not to that group, it seems, but rather to the property that is necessary for inclusion in that group: wisdom. It is controversial whether we really need to populate our universe with strange objects such as 'properties' and 'universals'; but, in any case, even if they do exist, it's not clear that ordinary predicates refer to them. For example, 'wisdom' may be the name of a particular thing, referred to in the sentence, 'Wisdom appeals to Francine,' but it is much less clear that this thing is

referred to in the sentence 'Spinoza is wise.' A similar difficulty is posed by common nouns, e.g., 'philosopher.' It does not seem that we could explain the meaning of this element in the sentence 'Spinoza is a philosopher' by claiming reference to a particular philosopher, the class of philosophers, or philosopher-ness.

Furthermore, reference has nothing to do with grammatical structure, which one would think is an important part of the meaning of any sentence. These two sentences, 'Jane loves John' and 'John loves Jane,' make the same references (to Jane, John, and loving, perhaps) but they surely mean something very different. A sentence conveys more than a series of references. It does not merely point at Jane, John, and the property of loving; in addition, it makes the claim that Jane loves John (or vice versa).

Meaning as Truth Conditions

Perhaps a more promising way to extend the reference theory for common nouns, predicates, and other linguistic elements is to think of them as functions. Consider the analogy with arithmetic: 5, 13, −9, and so on are the names of numbers (whatever they are), but $x/3 = 9$ is a function from numbers to a 'truth value.' With '27' as the argument, its value is TRUE. With '16' as the argument, its value is FALSE. Its meaning consists in the systematic way in which it pairs arguments with truth values. Now consider the systematic way 'x is wise' relates arguments to truth values. Substitute the proper name of certain things (any of the wise things) and the value is TRUE. Substitute the proper name of other things and the value is FALSE. The systematic way in which arguments and values are related in this case (it seems) exhausts the meaning of 'is wise.' Philosophers have proposed similar ways to deal with other linguistic elements. For example, adverbs might be regarded as functions taking a predicate as 'argument' and yielding a predicate as 'value.'

This amendment in the spirit of the direct reference theory considerably extends its power and explains the function, basically in terms of reference, of various parts of language that do not by themselves refer. Partially because some of the functions in this approach have TRUE and FALSE as values, it was proposed that these truth values be considered the referents of sentences. (This move has seemed implausible to many, however: what are these things called truth values?)

In the 1930s, Alfred Tarski proposed a definition of 'truth' that some philosophers thought would be the basis of a good theory of meaning. Tarski's proposal was that what would constitute a definition of TRUE for a language *L* would be a complete list of statements giving the truth conditions for each of the sentences in *L*. So one of these statements defining truth-in-English would be '*Snow is white' is true in English if and only if snow is white*. (This may appear ludicrously trivial, because the sentence whose truth conditions are being given, and the reference to the truth condition itself, are in the same language. Of course, if you did not know what made 'Snow is white' true, this statement would not tell you. But that is not a problem with Tarski's view in particular: no statement of a theory would be informative to somebody who didn't speak the language in which the theory was stated.)

Now, when we know the truth-conditions for a sentence, then do we know its meaning? Once you know, for example, what it takes to make 'Snow is white' true, then, it seems, you know what that sentence means. And what it takes, after all, is that snow be white.

Obviously what one learns when one learns the meaning of a language cannot be the truth conditions of each sentence in the language, one at a time, because there are an infinite number of sentences. What is learned must be the meanings of a finite number of elements of sentences, and a finite variety of structures they go into. In the Tarskian view, then, the semantic theory of a language consists of a large but finite number of elements (words, perhaps), together with composition rules for putting them together into sentences and information sufficient for deriving the truth conditions for each of a potentially infinite number of sentences.

One might object that this elaborate theory could not be what people know when they know what their language means. But perhaps providing this is not the purpose of a semantic theory (or a theory of anything). Baseball players are adept at predicting the path of a ball but only rarely are familiar with Newtonian theory of falling bodies.

The idea here is attractive. If you know what sort of world would make a sentence true, then it seems that that is all it would take for you to know what that sentence means. This idea (though not particularly through Tarski's influence) was the basis of the 'logical positivist' theories of meaning and of meaningfulness. Logical positivists enjoyed pointing out that Heidegger's famous assertion "*Das Nicht nichtet*" ('The nothing nothings') was associated with no particular ways the world might be that would make it either true or false, and concluded that this statement, along with many others in metaphysics (e.g., McTaggart's assertion that time is unreal), were meaningless. But it seemed that baby and bathwater alike were being flushed down the drain. Coupled

with a rather narrow and ferocious empiricism, this criterion ruled out as meaningless a number of assertions that were clearly acceptable. What empirical truth conditions are there **now** for statements about the past, or for assertions about invisible subatomic particles? But this may be a problem more about the logical positivists' narrow empiricism than about their theory of meaning/meaningfulness. More germane here is the problem that many perfectly meaningful sentences have no truth conditions because they're neither true nor false: 'Please pass the salt,' for example.

Sense and Reference

Because of the Hesperus/Phosphorus problem mentioned above, Frege rejected the idea that the meaning of an expression is the thing it refers to. So Frege distinguished the thing to which a symbol referred (in his words, the *Bedeutung*, the 'referent' or 'nominatum') from what he counted as the meaning (the *Sinn*, usually translated as the 'sense') of the symbol, expressed by the symbol. The sense of a symbol, according to Frege, corresponded to a particular way the referent was presented. It might be called the 'way of thinking about' the referent. While his theory separated meaning from reference, nevertheless it can be considered a 'mediated reference theory': senses are ways a reference would be encountered, ways of getting to things from the words that refer to them. But it is the reference of included terms, not their sense, that determines the truth value of the sentence.

Frege's approach led him to a problem with sentences such as these:

(1) Fred said, "Venus is bright tonight."
(2) Fred believes he's seeing Venus.

Both sentences include examples of 'opaque context,' a part in the sentence in which substitution of a co-referring term can change the truth value of the sentence. In each of these sentences, substituting 'the second planet from the sun' for 'Venus' may make a true sentence false, or a false one true. In (1), an example of 'direct discourse,' if Fred's very words did not include 'the second planet from the sun,' then that substitution can make a true sentence into a false one. That substitution in (2) may result in a false sentence if Fred believes that Venus is the third planet from the sun. Frege's solution to this problem is to stipulate that in direct discourse – word-for-word quotation – the expression quoted refers to 'itself,' rather than to its usual referent (in this case, Venus). And in belief contexts and some other opaque contexts, expressions refer to their 'senses,' not to their usual referents.

But what, exactly, are these 'senses'? First, it is clear that Frege did not intend them to be the ideas anybody associates with words. Frege's 'senses' are objective: real facts of the language whose conventions associate senses with its symbols. One may have any sort of association with a bit of language, but the conventions of the language specify only certain of them as meaning-related. (Therefore, Lewis Carroll's Humpty Dumpty does not succeed in meaning 'There's a nice knock-down argument for you' with 'There's glory for you,' even though he insists "When I use a word it means just what I choose it to mean – neither more nor less.") But why not admit that in addition to the public languages there can be 'private' ones with idiosyncratic senses? More will be said about this later.

But second, neither can 'senses' be characteristics of the things referred to: for then, whatever is a sense of 'Hesperus' would be a sense of 'Phosphorus.' Furthermore, there appear to be symbols in a language that have sense but no reference: 'the present king of France' and 'Atlantis' are examples. Reference-less terms pose a problem for Frege. Should he consider them words with sense but no reference? If so, then how can they figure in sentences with a truth-value? (This is similar to the 'Santa Claus' problem.)

A promising approach seems to be to say that the sense of a term 'T' consists of those characteristics judged to be true of things that are called 'T' by competent speakers of the language. But this immediately creates a problem with proper names. If ordinary proper names have senses – associated characteristics that are the way of presenting the individual named, associated conventionally with that name by the language – then there would be corresponding definitional (hence necessary) truths about individuals referred to by proper names. But this is problematic. The sense of a name applying to one individual cannot be the sense of the name of any other individual, because senses are the way terms pick out their designata. So the characteristics associated with a name would have to constitute that individual's 'individual essence' – characteristics uniquely and necessarily true of that individual. But many philosophers have doubted that there are any such characteristics. Even if we can find characteristics that uniquely designate an individual, Kripke (1972) influentially argued that these characteristics are never necessary. Suppose, for example, that 'Aristotle' carries the sense 'Ancient Greek philosopher, student of Plato, teacher of Alexander the Great.' It would follow that this determined the referent of 'Aristotle'; so if historians discovered after all that no student of Plato's ever taught Alexander the Great, then 'Aristotle' would turn out to be a

bearer-less proper name, like 'Santa Claus.' But this is not how the proper name would work. Instead, we would just decide that Aristotle did not teach Alexander after all. Kripke argues that all sentences predicating something of a proper-named individual are contingent, so proper names do not have senses. But, of course, they are meaningful bits of language.

This problem may apply even more broadly than merely to proper names. Consider the meaning of the term 'water.' Back before anyone knew the real properties of what made water water – i.e., its chemical constitution – competent speakers applied the term to any colorless, odorless liquid. But they were sometimes wrong, because the characteristics then used to distinguish proper and improper applications of the term, although they happened to pick out water on the whole, were not the genuinely necessary and sufficient conditions for something to be water at all. In those days, then, the real sense of the word was totally unknown and unused by any competent speaker of the language.

Quine argued that Frege's senses lack what is necessary for well-behaved theoretical objects. We have no idea, for example, of their identity conditions: is the sense of this word the same as the sense of that? More about Quine will be discussed in the final section of this article.

The Idea Theory

The theories discussed so far consider what linguistic elements mean, but other classical theories have concentrated on what people mean by bits of language.

Words, Locke argued, are used as 'sensible marks' of ideas; the idea corresponding to a word is its meaning. This has a certain amount of intuitive plausibility, in that non-philosophers think of language as a way of communicating ideas that is successful when it reproduces the speaker's idea in the hearer's mind.

The 'idea theory' of meaning received its fullest expression in conjunction with British Empiricist epistemology. For the classical empiricists, our ideas were copies of sense-impressions – presumably similar to the sense experiences themselves, except dimmer. These mental representations served us as the elements of thought and provided the meanings for our words.

However, problems with this theory are obvious. For one thing, not every such association is relevant to meaning. For example, the word 'chocolate' makes me picture the little shop in Belgium where I bought an astoundingly impressive chocolate bar. But although one might want to say, in a sort of loose way, that that's what 'chocolate' means to me, it doesn't seem to be a real part of the word's meaning. Someone else could be completely competent in using that word without any mental pictures of Belgium.

Also, there are some meaningful terms that seem to be associated with no mental imagery, for example, 'compromise.' The problem of the meaning of 'unicorn' is solvable: images of a horse's shape and an antelope's horn can be mentally pasted together to provide a representation; but there are other problems. My image of my cat Tabitha might picture her facing right; but I'm to use this also to identify her as the bearer of that name when she's facing left; so the mere association of a word with an image is not enough to give that word meaning. There must also be some procedure for using that image. Common nouns ('dog') could stand for any and all dogs, whereas the meaning of 'dog' was presumably a particular image of a particular dog. More of a theoretical mechanism is needed to explain why this image stands for Fido and Rover but not for Tabitha. And other sorts of words – logical words, prepositions, conjunctions, etc. – raise problems here too: how could sensory experiences be the source of **their** meaning?

A more recent concern about the idea theory arose from the fact that the ideas that gave bits of language their meaning were private entities, whereas the meanings of a public language were presumably public. Clearly I would learn the word 'cat' by hearing you use the word in the presence of cats, but not in their absence; but according to the idea theory, I would have learned it correctly when my private image matches yours – something that is impossible for either of us to check. What we can check – identical identifications of objects as cats and non-cats – does not ensure identical private imagery and (according to the idea theory) has nothing directly to do with the meaning we invest 'cat' with anyway. Wittgenstein's 'private language argument,' deployed against the idea theory, was considered devastating by many philosophers. Very briefly put, this argument is that the meaning of a public bit of language could not be given by a supposedly necessarily private item, such as a mental representation, because this would make impossible any public check – any real check at all – on whether anyone understood the meaning of a term; and without the possibility of a check, there was no distinction between getting the meaning right and getting it wrong.

Meaning as Use

Wittgenstein's hugely influential suggestion was that we think instead of sentences as "instruments whose senses are their employments" (1953: 421). Starting in the 1930s and 1940s, philosophers began thinking

of the meaning of linguistic items as their potential for particular uses by speakers and attempting to isolate and describe a variety of things that people do with words: linguistic acts, accomplished through the use of bits of language. One clear theoretical advantage of this approach over earlier ones was its treatment of a much wider variety of linguistic function. Whereas earlier approaches tended to concentrate on information giving, now philosophers added a panoply of other uses: asking questions, giving orders, expressing approval, and so on. This clearly represented a huge improvement on the earlier narrower views, which tried to understand all the elements of language as signs – representations – of something external or internal.

Austin distinguished three kinds of things one does with language: (1) the 'locutionary act,' which is the utterance (or writing) of bits of a language; (2) the 'illocutionary act,' done by means of the locutionary act, for example, reporting, announcing, predicting, admitting, requesting, ordering, proposing, promising, congratulating, thanking; and (3) the 'perlocutionary act,' done by means of the illocutionary act, for example, bringing someone to learn x, persuading, frightening, amusing, getting someone to do x, embarrassing, boring, inspiring someone. What distinguishes illocutionary acts is that they are accomplished just as soon as the hearer hears and understands what the utterer utters. It is clear that the illocutionary act is the one of these three that is relevant to the meaning of the utterance. The performance of the act of merely uttering a sentence obviously has nothing to do with its meaning. Neither does whatever perlocutionary act is performed: you might bore someone by telling her about your trip to Cleveland or by reciting 75 verses of *The fairie queen,* but the fact that both of these acts may serve to bore the hearer does not show that they are similar in meaning. But similarity in meaning is demonstrated by the fact that two different locutionary acts serve to accomplish the same illocutionary act. For example, 'Do you have the time?' and 'What time is it, please?' perform the same illocutionary act (a polite request for the time) and are thus similar in meaning.

However, this approach does not deny that what the other theories concentrated on is a significant part of language. In Austin's classification, one part of many locutionary acts is an act of referring; when I say, "Aristotle was the student of Plato," I'm probably performing the illocutionary act of informing you, but I'm doing that by means of the locutionary act of referring to Aristotle and Plato. And clearly many linguistic acts include 'propositional content': one reports, announces, predicts, admits, requests, orders, proposes, promises, and so on, 'that p,' so it seems that inside this theory we would need an account of the way any of these linguistic acts correspond to actual or possible states of the world.

A recent influential theory from Donald Davidson responds to these needs by combining, in effect, speech act theory with Tarskian semantics. According to Davidson's proposal, the list of truth conditions for each assertion in a language provides an account of the language's semantics – at least, of the propositional content of sentences in the language: what a statement, prediction, assertion, question, etc., states, predicts, asserts, asks, etc. This explains what is shared by 'The light is turned off,' 'Turn off that light,' 'Is the light turned off?' and so on. But secondly, according to Davidson, a theory of meaning needs a 'mood indicator' – an element of the sentence that indicates the use of that sentence – e.g., as a statement, request, or question.

Quine's Skepticism

Quine's skepticism about meanings was among the most important 20th-century developments in the philosophy of language. Here is one way of approaching his position. Imagine a linguist trying to translate a tribe's language. Suppose that the tribesmen said "*gavagai*" whenever a rabbit ran past. Does '*gavagai*' mean 'lo, a rabbit!'? The evidence might as well be taken to show that '*gavagai*' asserts the presence of an undetached rabbit part, a temporal slice of a rabbit, or any one of a number of other alternatives, including even 'Am I ever hungry!' or 'There goes a hedgehog!' (if the tribesmen were interested in misleading you). Quine called this the 'indeterminacy of translation.' But, we might object, couldn't further observation and experimentation decide which of these alternatives is the right interpretation? No, argued Quine, there are always alternatives consistent with any amount of observation. But, we might reply (and this is a more basic objection), what that shows is that a linguist never has absolutely perfect evidence for a unique translation. This is by now a familiar (Quinian) point about theory: theory is always to some extent undetermined by observation. In any science, one can dream up alternative theories to the preferred theory that are equally consistent with all the evidence to date. But in those cases, isn't there a right answer – a real fact of the matter – which, unfortunately, we may never be in a **perfect** position to determine, because our evidence must always be equivocal to some extent? At least in the case of meaning, argued Quine, the answer is no, because for Quine, linguistic behavior is all there is to language, so there are no hidden facts about meaning to discover, with linguistic behavior as evidence. So

meanings are not given by ideas in the head, Fregean senses, or anything else external to this behavior.

A similar sort of position was argued for more recently by Kripke (1982). Imagine that someone – Fred – has used a word 'W' to refer to various things, A, B, and C. Now he encounters D: is that referred to by 'W'? One wants to say: if D is like A, B, and C, then Fred should go on in the same way and apply 'W' to D. But Kripke argues that there is no fact about Fred's intentions or past behavior – no fact about what he means by 'W' – that would make it correct or incorrect for him to apply 'W' to D. Neither is there, in the external world, a real sufficient (or insufficient) similarity of D to A, B, and C that make it correct (or incorrect). The only thing that would make that application correct or incorrect is what a community of speakers using that word would happen to agree on.

But does anti-realism about meaning really follow from these considerations? Suppose that Quine and Kripke are right, and all there is to language is social behavior. But maybe this does not imply that meanings are unreal. When we consider an action as social behavior, after all, we do not think of it (as Quine, in effect, did) merely as bodily movements. There are facts about the social significance of the behavior, above and beyond these movements, that give the movement its social significance. Perhaps it is these facts that would make one linguistic theory rather than another correct – that determine the meaning of the noises made by Quine's natives, and whether Fred is following the linguistic rule when he applies 'W' to D. Language is a tool we know how to use, and the real meaning of our utterances is what we know when we know how to use that tool.

Early Theories of Meaning

The problem of the basis on which linguistic signs mean something and can designate real objects or relations is a central subject of theories of language. The starting point of debates on this matter might be the dialog *Cratylus* by Plato (428/7–349/8), in which two opposite positions are contrasted: the conventionalist position (*thesei*), which ascribes the imposition of names to a voluntary convention between people, and the naturalist position, which supposes a natural denomination of an object depending on its properties (*physei*). Plato introduced Socrates (470/69–399) as a mediator between these two positions and presented them as complementary.

For Aristotle (384/3–322), names are *kata syntheken*: unlike the unarticulated sounds of animals, they are historically imposed. The Aristotelian concept of the sign, which corresponds to the notion of arbitrariness in later theories, implies semantic function as well as the relation between the name and the designated reality. During the following centuries, several changes brought to the fore this relation between sounds and objects and its genetic explanation and partially disregarded the question of how signs mean something. The idea that linguistic signs were not naturally motivated, but invented by voluntary imposition, found different expressions (*non natura sed ad placitum, ex arbitrio, arbitrarius, willkürlich, arbitraire, arbitrary*).

The explanation of the semantic function could then concentrate on the description of this voluntary imposition. For the medieval authors of *modi significandi* a sound (*vox*) became a word by its meaning (*ratio significandi*). The bilateral character of the linguistic sign was expressed in this context by the opposition of *significatum* and *quod significatur*, which appeared in several variations (Thomas of Erfurt, *Grammatica speculativa*, I, §3: *signum, vel significans*; Martinus de Dacia: *res designata/vox significans*).

The relation between both sides of the linguistic sign was presented as a problem by nominalist theories. The Logic of William of Ockham (1285?–1349?) was mainly based on semantic observations of expressions that have meanings. The signification, corresponding to the result of the previous formation of concepts, was differentiated into suppositions concerning the actual and contextual relation of a sentence. In this manner, the *significatio* as a potential of meaning was opposed to the *suppositio*, the actualized meaning. This consideration of meaning by the nominalists implied a higher degree of independence of meaning with regard to reality.

The doctrine of St. Augustine (354–430) led to another conception of meaning and its relation to reality. A main tenet of the Augustinian rationalist doctrine was the merely spiritual nature of all notions and of the relations between them. The denotation of a term was regarded as a mental object that could only have a representational relation to the word and could not depend on linguistic signs and their corporeal nature. The form words obtain in the different languages was regarded as arbitrary, whereas the composition of the concept was universal and did not depend on sensations. For the rationalist thinkers, the necessity of language appeared only with communication between people when the transmission of pure incorporeal notions was impossible. But linguistic signs met the necessities of communication in a very insufficient way because intuitive conceptions overwhelmed our mind, whereas their linguistic signs distracted from their content and slowed down the process of thinking. Although words had different forms in different languages, the ideas designated were neither Greek nor Latin but universal and independent of any sensual support.

This rationalist theory limited the impact of language on cognition and, in the same way, the trustworthiness of sensory cognition. But in some authors we find the opposite perspective. Let us mention the Spaniard Luis de León (1527–1591), who wanted to achieve knowledge about the nature of religious concepts by studying the denominations of Christ in the Bible. The basis of his *De los nombres de Cristo* was a semantic theory that supposed a capacity of representation of the denominated (*nombrado*) by the name (*nombre*) in cognitive processes.

By the separation of the original status of language from the development of historical languages, the validity of the biblical doctrine on the origin of language was clearly established and the possibility of reflection on arbitrary signs based on human reason was opened.

Intension and Extension in Port-Royal Logic

The Grammar (1660) and the Logic (1660) of Port-Royal took up and developed semantic concepts that exercised an important influence on the further development of semantic theories. The authors of the Port-Royal Logic, Antoine Arnauld (1612–1694) and

Pierre Nicole (1625–1695) treated the problem of the arbitrary sign in its complexity, regarding words not as natural (*signes naturels*) but as conventional signs that functioned as grounded on tradition (*signes d'institution et d'établissement*). But the establishment of a convention presupposed the existence of already formed ideas, which could be denominated by words chosen conventionally.

The primacy of thought set prerequisites for the interpretation of arbitrariness. What could be regarded as arbitrary were not ideas themselves but only the attribution of sounds to these ideas, which would exist even without them. The meanings of the linguistic signs did not appear in the moment of their conjunction with sounds but, rather, they existed as clear and reasonable ideas and were independent of their denomination. The fact that convention varied in different languages could prove easily that it had nothing to do with the nature and formation of ideas. But this conclusion, which derived from the rationalist thesis of innate ideas, was not the only restriction on the arbitrariness of signs. The authors of the Logic declared that the relation between sound and meaning was only arbitrary in the individual use of language but that it was determined by common use through communication between people.

It seems remarkable that the assignment of sounds to meanings was regarded as a relation between two mental entities. The idea of the psychological nature of both sides of the linguistic sign is obviously not a product of the beginning of the 20th century.

In the examination of meaning, Arnauld and Nicole distinguished the intension (*compréhension*) and the extension (*étendue*) of a sign. By intension they meant the totality of features that constituted an idea, none of which might be taken away without destroying the idea. Extension was defined as the totality of objects, notions, and subnotions to which an idea could refer. What determined the identity of a meaning was not its reference to different objects and notions but the intension. Although it was always possible to limit the extension of a word, leaving out a feature of its intension would make it lose its identity.

The reference point for the intensional definition of meaning was language as a product and not its use in communication. The meaning was obligatory in its features and was determined by convention, whereas the extension depended on the use of the word to denote either a whole class of objects or an individual.

The discussion of the actualization of conventional signs in use leads to another distinction in the Port-Royal Logic. Arnauld and Nicole distinguished between a proper meaning (*signification propre*) and accessory ideas (*idées accessoires*). The latter derived from the dynamic character of meaning in communication in which accessory ideas were evoked. For exampal, the sentence *you have lied* has the same principal (proper) meaning as *you know that the contrary of what you are saying is true*, but it evokes the accessory ideas of insult and contempt. Accessory ideas were not ascribed to a word by common use, but they appeared in the individual use of language. Repetition could lead to generalization of such accessory ideas and, as the result of this process, accessory ideas might be linked habitually to words, especially to synonyms. But in this case, we would have to take into account the inconsistency of such accessory ideas.

The differential function of the accessory ideas was highly estimated by the authors of Port-Royal. They even demanded to explain them in dictionaries. This assertion of distinct words with similar meanings helped to prepare dictionaries of synonyms that became popular in many European countries.

Arnauld and Nicole also discussed oppositions and proposed a classification of them. They called 'divisions' such pairs of opposites that covered the whole extension of a notional field and could be related to a hyperonym (*pair/impair* → *nombre*). In cases in which the opposites were divided by a zone of indifference, they even described the field of this zone, including the antonyms in a narrow sense (Table 1). The confusion of these two types of oppositions was regarded as harmful for logical conclusions, if a person took the negation of a term as its opposite and did not take into account the zone of indifference. For a further differentiation, Arnauld and Nicole gave the terms of opposites shown in Table 2.

The Logic of Port-Royal contained a comprehensive theory of different semantic oppositions and even attempts at a systematic description of the vocabulary.

Table 1 Opposites and zones of indifference

Opposites	*Zone of indifference*
sain/malade	indisposé, convalescent
jour/nuit	crépuscule
avarice/prodigalité	libéralité, épargne louable, générosité

Table 2 Kinds of oppositions

Name of the opposition	*Examples*
Termes relatifs	père/fils, maître/serviteur
Termes contraires	froid/chaud; sain/malade
Termes privatifs	vie/mort; vue/aveuglement
Termes contradictoires	voir/ne pas voir

The Recognition of the Historical and Cultural Nature of Meaning

The Recognition of the Genius of a Language

At the end of the 17th century, the notion of the genius of the language (*génie de la langue*) became very fashionable. It appeared in systematizations of Vaugelas's *Remarques sur la langue française* by Louis Du Truc (1668), Jean Menudier (1681), and Jean d'Aisy (1685) and was taken up by grammarians and philosophers as well.

The 'Essay concerning human understanding' (1690) by John Locke (1632–1704) gave a new answer to the question of how thought could be influenced by language. According to Locke, linguistic signs did not represent the objects of knowledge but the ideas that the human subject created. The nominalist explanation of complex ideas led to the denial of innate ideas and to the supposition of a voluntary imposition of signs on a collection of simple ideas for which there was no pattern in reality. This rendered possible an extension of the concept of arbitrariness to the composition of meaning. Language was no longer regarded as a simple expression of a universal reason but as a system that organized thought following historical and social principles.

Bernard Lamy (1640–1715), who was influenced by the Port-Royal authors but found a way to integrate their theory into the assertion of a sensual basis of human cognition, remarked on the different division of lexical areas in various languages. In his Rhetoric (*La rhétorique ou l'art de parler*, 1699), he explained the quantity and differentiation of words by the attention different peoples give to some fields of knowledge. In this way, he explained the existence of more than 30 words to denote 'camels' in Arabic as well as the fact that people who cultivated the sciences and arts had a developed and highly differentiated vocabulary. Especially in the formation of diminutive and augmentative denominations, languages differed considerably: In Italian, for example, many diminutives had developed, whereas they were absent in French.

Because languages used different points of view in the denomination of things and concepts, a word-by-word translation from one language into another was nearly completely impossible. This was an opinion that was largely shared by 18th-century authors. If a person looked at the motives for the formation of words, the differences between languages became even more obvious. Lamy used an old example for the argumentation on this subject: the words for 'window' in the Romance languages that are derived from three Latin etyma. The Spanish *ventana* (< *ventus*) emphasizes the blowing of the wind, the Portuguese *janela* (< *janua*) uses a comparison with a gate, and the French *fenêtre* (< *fenestra* < Greek *φαινειν* 'to shine') uses the transmission of light. This meant that the same word, which stood for a fundamental idea, had different significations in different languages.

The Study of Metaphors

With the positive evaluation of the cognitive force of sensation and emotional speech, the problem of metaphors became more important. César Chesneau de Du Marsais (1676–1756) dedicated a digression in his book *Des Tropes ou des différents sens dans lesquels on peut prendre un même mot dans une même langue* (1730) to the study of metaphors and idioms in various languages. He started with the difficulties of translation of lexical metaphors and the lack of assistance from dictionaries. Although it was possible to find an equivalent for the proper meaning (*sens propre*) for which the word had originally been installed, it was often impossible to translate all the figurative meanings (*sens figurés*) of words. The use of words in their metaphorical meaning was not regarded as an exception. Naming an idea by a sign that was related to an associative idea was a regular case in language. In addition, the use of words in their figurative meanings could fill the gaps in vocabulary.

The French word *voix*, for example, had, in addition to its proper meaning 'the sounds emitted by the mouth of animals, and especially by human mouth,' several figurative senses: (1) 'inner inspiration or pangs of conscience' in the sentence *le mensonge ne saurait étouffer la voix de la vérité dans le fond de nos cœurs* ('the lie will not be able to suffocate the voice of truth in the deep of our hearts'), (2) 'inner sensations' in word groups such as *la voix du sang* ('the voice of blood') and *la voix de la nature* ('the voice of nature'), and (3) 'opinion, view, judgment.' Not all of these figurative meanings of *voix* could be translated by the Latin word *vox*. In the same manner, it would not be possible to translate *porter* 'to carry' by *ferre* in the case of figurative uses such as *porter envie*, *porter la parole*, and *se porter bien*. Du Marsais criticized the usual practice in French-Latin dictionaries, which gave just a series of verbs (in the case of *porter*: *ferre*, *invidere*, *alloqui*, *valere*) without mentioning the specificity of their semantic qualities. If dictionaries continued in this way, they might arrive at the explanation of *aqua* 'water' by *feu* 'fire,' simply because the cry for help regarding a fire in Latin was *aquas aquas* and in French *au feu*. From a certain referential meaning of a word, it was not possible to infer its essential semantic property. As Du Marsais

claimed, dictionaries should first of all give the *significations propres* and then explain the figurative meanings that could not be deduced from the proper one. This explanation should be given by examples and by grouping the figurative meanings according to the given state of language. But a historical explanation of figurative meanings should also be possible because all of them developed out of the proper meaning that was regarded as the original one. The manner of such a development might differ in various languages, which would lead to a complicated picture of the relations between figurative meanings of words in two languages.

In his *Fragment sur les causes de la parole,* Du Marsais arrived at an important theoretical conclusion concerning the semantic function of words. He supposed meaning to be a systematic virtual property of language and opposed it to the realizations of words and their meanings in language use. The systematic property, called la *valeur des mots* by Du Marsais, was acquired by education and contact with other people. It corresponded to an abstraction of the different senses a word might have.

The Study of Synonymy

The study of synonymy in 17th- and 18th-century linguistics did not concern just supplying different means for the expression of the same idea but mainly differentiating the meanings of synonyms and determining the exact definition of the meaning of every single word. In addition to the theoretical interest that synonyms as a simple systematic phenomenon represented, practical needs contributed to the study of synonymy. The starting point was the doctrine of a *verbum proprium*, an appropriate word for each purpose, which should be defined by its invariable semantic properties. Defining synonyms became an aristocratic game in France in the 17th century and was disseminated throughout Europe.

The most influential work was written by Gabriel Girard (1777/8–1748) (*La Justesse de la langue française, ou les différentes significations des mots qui passent pour synonymes*, 1718; *Synonymes français, leurs significations et le choix qu'il faut en faire pour parler avec justesse*, 1736). Girard declared explicitly that the language of a certain state formed a system, despite the unsystematic character of the formation of languages. In this context, he defined the *valeur* of a word as its correct meaning, which corresponded to the current use in the language. He started from a rationalistic position and supposed that ideas were independent of language and only had to be denominated by words. The *valeur* of a word consisted in the representation of ideas that the language use had related to it, and therefore it was determined by a social convention or an explicit individual imposition.

But in the description of synonyms, Girard mainly regarded the differences of their values. Following his approach, synonyms were words that expressed a common idea but were distinctive in the expression of accessory ideas. The similarity of their meanings did not encompass the whole area of their significations. The accessory ideas gave a special and proper character to every synonym and determined its correct use in a certain situation.

The richness of a language was therefore not only determined by a multitude of words but by the distinctions between their meanings and by precision in the expression of simple and complex ideas. In Girard's system of synonyms, only the *valeur* counted, and it was described by the relations of a synonym to words with similar significations. He rejected the opinion that synonyms should only help to avoid monotony by variation in sound.

In the practical distinction of synonyms, Girard presented the similarities and distinctions of synonyms using the *genus proximum–differentia specifica* scheme of antiquity and scholasticism. He tried not to create differences that could not be observed in language use; however, in many cases he attempted to establish a logical relation between synonyms, for example, a gradation (*ordinaire, commun, vulgaire, trivial*), a purpose-means relation (*projet – dessein*), or causal relations (*réformation – réforme*).

Girard's description of complex lexical structures showed that the term *synonymy* could be used in 18th-century texts for lexical fields and their structure. The words designated as synonyms could be different in their intension and extension, showed use restrictions, or entered into various oppositions. On this basis, Girard distinguished the elements of the semantic field of intellectual qualities, establishing semantic compatibilities and determining features of meaning for every word. Apart from a substantial description of the meaning of words, Girard also supplied oppositions, such as:

esprit – bêtise
raison – folie
bon sens – sottise
jugement – étourderie
entendement – imbécilité
conception – stupidité
intelligence – incapacité
génie – ineptie

In Girard's doctrine, the value (*valeur*) of a word is a use-independent semantic property that could be

described by its relations to other words. In the use of language, it allowed different significations to be produced.

Girard's approach was widely disseminated in Europe. It was used, for example, by Johann August Eberhard (1730–1809) in his *Synonymisches Handwörterbuch der deutschen Sprache für alle, die sich in dieser Sprache richtig ausdrucken wollen* (1802). In Spain, synonymy became an important field of discussion, as expressed in works such as the *Ensayo de los synonimos* by Manuel Dendo y Avila (1756).

Condillac's and the Idéologues' Semantics

Etienne Bonnot de Condillac (1714–1780) formulated a coherent sensationalist theory of cognition by substituting for Locke's dualist explication of sensation and reflection the concept of transformed sensation (*sensation transformée*), which helped to explain even complex thought as being made up of simple sensations. The instrument allowing this transformation was language, to which Condillac attributed an important role in human thought. The signs of human language operated according to the principle of analogy, which corresponded to a motivated relation between signs of analogous content.

Instead of *signes arbitraires,* and in order to emphasize the genetic character of language, Condillac used the term *signes d'institution*, finally preferring in his Grammar (1775) the denomination *signes artificiels*. An arbitrary relation existed not only between sounds and the ideas related to them but in the composition of complex ideas. This arbitrariness was relativized by the long historical process of imposition of signs, in which a language evolved its specific shape or genius. This specificity concerned the functions of languages as analytic means and it became important in the discussions of the Ideologues of the end of the 18th century.

The linguistic ideas of the Idéologues have mainly been studied in relation to theories they took up and modified, as well as from the point of view of the continuation of their legacy by later linguistic theorists. Whether the Idéologues really were representatives of a transitional thinking that rendered possible the explication of the school grammar categories of the 19th and 20th centuries has also been discussed. They were considered, moreover, as the starting point and the background for several theoreticians, for example Wilhelm von Humboldt (1767–1835) and Ferdinand de Saussure (1857–1913), for whom language was, above all, an instrument of the articulation of thought. But the Idéologues themselves did not admit that they had much continuity with the theory of Condillac; they even stressed their independence from all previous authors. This was an expression of a break with mechanical education.

Meaning in 19th-Century Linguistics

General Evolution

In this section we do not follow the fascinating history of reflection on meaning in general and on the meaning of words in particular in the 19th century; instead, we examine some approaches to semantic description. In the 19th century, the fascination with meaning led to a sudden increase in the number of books, treatises, and pamphlets on semantic topics, in the widest sense of the term. Books on words were widely read and shaped the popular image of semantics, thereby undermining its claims as a science. Even Bréal's *Essai de sémantique* (1897) was regarded as entertaining or amusing. Conversations on etymology contributed to this general soft image of semantics in a century that is now considered the advent of historical and comparative linguistics, with a focus on the discovery of sound laws.

Nevertheless, during the 19th century semantics was a very productive field. It led to innovations and went through three phases or stages (see Nerlich, 1992: 3). During the first stage, questions about the origin of language (see the previous discussion of the proper signification, the *Grundbedeutungen,* or original meanings) were gradually replaced by the problem of a continuous evolution or transformation of language and meanings. The search for a true meaning was abandoned in favor of the search for the types, laws, or causes of semantic change. It was claimed that the meaning of a word was not given by its etymological ancestry but by its current use, and that omitting etymology was an important factor in the functioning and evolution of language. During the second stage, questions about the types and causes of semantic change were slowly replaced by reflections on the mechanism of communication, comprehension, and linguistic interaction between speakers and hearers in a particular situation or context. During the third stage, semantics merged with what we now call pragmatics; word meaning was seen as an epiphenomenon of the sentence meaning.

Even though these three stages did not emerge neatly separated, profound changes took place. Semantics shed its early historical ties to comparative philology to become more and more attached to other fields, such as psychology and sociology.

The history of semantics in the various countries did not, in any way, unfold simultaneously. There

were also major differences among influences on the development of semantics, stemming from various philosophical traditions, on the one hand, and from the various natural sciences (biology, geology, medicine, etc.), on the other. Finally, the development of semantics differed by the influence of other linguistic disciplines and fields such as rhetoric, classical philology, comparative philology, and grammar, in general, and etymology, lexicography, and phonetics, in particular.

The birth of semasiology in Germany and sematology in England almost coincided. Semasiology was brought into being by Christian Karl Reisig's (1792–1829) lectures, given in the 1820s and posthumously published in 1839; sematology was founded with the publication of Benjamin Humphrey Smart's (1786–1872) treatise on sign theory, *Outline of sematology* (1831). In Germany, the maturation process of the discipline started with the edition of Friedrich Haase's (1808–1867) lectures on semasiology in 1874, followed by the re-edition of Reisig's work from 1881 to 1890. In England, sematology matured when, in 1857, the Philological Society of London decided to embark on a huge project: the New English Dictionary.

In 1831, Smart already noted the similarity and difference between French Ideology and his sematology. Both were theories of signs, but French Ideology studied the development of ideas in isolation, whereas Smart was interested in the context and in meaning construction.

At the end of the 19th century, a group of linguists adhered strictly to the doctrine of August Schleicher (1821–1868) and regarded linguistics as a natural science and language as an evolving organism. Similar metaphors were also used by Émile Littré (1801–1881), already in 1850, and by Darmesteter (1887), although in Arsène Darmesteter's (1846–1888) case the influence of psychology on his semantic thought was soon outweighed by that of biology.

The psychological influence brought about a shift from an interest in the mere classifications of types or laws of semantic change to a search for the causes of semantic change. According to different versions of psychology, especially of *Völkerpsychologie* (psychology of people), developed by Heymann Steinthal (1823–1899) and Moritz Lazarus (1824–1903), on the one hand, and by Wilhelm Wundt (1832–1920), on the other, these causes were to be sought in different phenomena. Psychology became the midwife to the second and most successful kind of semantics, developed in France mainly by Michel Bréal (1832–1915). He too referred to Condillac and the conception of the sign put forward by the Idéologues, in order, however, to criticize those naturalists who saw language as a natural organism or studied the growth, life, and death of words. For Bréal, words as signs had no autonomous existence. They changed because they were signs of thought, which were created and used by the speakers of a language. In his lectures and articles, he argued, like William Dwight Witney (1827–1894) in the United States, against the German way of doing linguistics – the search for an *Ursprache* (original language) and the study of language as an organism. He excluded from his criticism only Franz Bopp (1791–1867), citing his work as an example of careful methodology.

Semasiology in Germany

Between 1830 and the end of the 19th century, it is possible to detect an increasing broadening of the field of semasiology, from the atomistic study of words and the rather ill-conceived classification of types of semantic changes toward the recognition of the importance of cultural and social factors and the acknowledgment of context as a factor in semantic change. The logico-historico-classificatory tradition (Reisig; Haase; and Ferdinand Heerdegen, 1845–1930) was followed by the psychological phase (Lazarus and Steinthal) and the further development of semasiology (Max Hecht, 1857–?). Another landmark was the *Völkerpsychologie* of Wundt, who made possible a psychological tradition in semasiology. At the turn of the century, the time was ripe for new ideas in semantics, whether developed in response to Wundt or independently of his work (e.g., by Hermann Paul, 1846–1921; Philipp Wegener, 1848–1916; Stücklein, 19th century; and Karl-Otto Erdmann, 1858–1931).

The Development of the Sémantique in France

For Bréal, the history of a language was not just an internal history; it was intimately linked to political, intellectual, and social history, where creation and change were at any moment our own work. In his lectures (1866–1868), he showed that the meaning or function of words could survive the alteration of form. The force countering the alterations and filling the gaps was the human mind.

Darmesteter asked himself what were the causes and laws of semantic change. The evolution of language at all its higher levels was based on what Darmesteter called, in accordance with Bréal, the disregard of etymology. What was here described as a loss of etymological adequacy was seen in *La vie des mots étudiée dans leurs sigifications* (1887) as the gain of an adequate signification for language use.

From Sematology to Significs in England

English semantics in the 19th century was not a theoretically well-established field. It consisted of two disjointed strands of thought (Nerlich, 1992: 207): sematology and semasiology. The first type of semantics was a predominantly philosophical one that emerged from thinkers such as Locke, John Horne Tooke (1736–1812), and Dugald Stewart (1753–1828), culminating in Smart. The second type was a predominantly practical one that sprang from lexicographers and etymologists such as Samuel Johnson (1709–1784), Noah Webster (1758–1843), and Charles Richardson (1775–1865), culminating in Richard Chenevix Trench (1807–1886), James Murray, and Walter William Skeat (1835–1912).

By the end of the century, Lady Victoria Welby (1837–1912) had rekindled philosophical interest in semantic questions and fostered a new approach to the problem of meaning. This approach was called significs and constituted a return to Smart's reflections on semiotics, but it lifted sematology, semasiology, and *la sémantique* onto a higher psychological, moral, and ethical plane.

Summary

To summarize this section (see Nerlich, 1992: 19), in Germany we can distinguish between two main approaches to semantics: an atomistic-historical attitude and a holistic-psychological one. In France, the historical *sémantique* sprang directly from psychological insights into language evolution. And in England, the psychological approach was marginal and the historical one dominant until the end of the century.

Media and Language: Overview

S McKay, University of Queensland, Brisbane, Australia

© 2006 Elsevier Ltd. All rights reserved.

The mass media are generally considered to include the press, radio, and television; the Internet, although not strictly a medium, is also increasingly included. News and current affairs articles and programs, documentaries, sports news and broadcasts, radio phone-ins, advertisements, reality television, quiz shows, soap operas, websites, and so on help to organize the ways we understand our society and culture. They are often the only way we have of understanding other societies and cultures. The media's influence on everyday life is usually taken for granted. They supply accounts of reality and construct particular forms of knowledge and pleasure: they inform and educate, they sell products, they tell stories, they entertain, they connect us with others, they help form our identities, they influence trends and mobilize opinion, they circumscribe our experience in what has become a media-saturated environment.

Linguists and others working in language and communication have always been interested in the language of the media. Bell (1995: 23) gives four reasons for this: the ready availability and accessibility of media texts as sources of language data; the importance of media for evidence of language use and language attitudes in a speech community; the use the media themselves make of language; and the way the media reflect culture, politics and social life. Not surprisingly, other researchers from a range of disciplines and fields such as media studies and journalism, communication, cultural studies, sociology, education, and psychology have also been interested in how the media shape these understandings. In these fields, media are studied not just through their texts but also through the wider cultural contexts associated with industrial production processes, and through the effects they have on their audiences (for example, Watson, 1998; Curran and Gurevitch, 2000). While texts are at the center of any concern related to language and the media, the analysis and critique of production processes and audience effects are often valuable as well. This article will discuss a variety of approaches to media analysis and outline briefly some of the recent debates about the media to emphasize the usefulness of the range of critical resources that have been applied to media texts and media language.

Approaches to Media Language Analysis

Media texts have been analyzed both quantitatively and qualitatively (*see* **Media: Analysis and Methods**). Early work, especially in the United States, concentrated on content analysis. Content analysis focuses on the message and assumes that its content can be broken down into units of meaning that can be counted in a process that is designed to be objective and replicable. Much of this early work looked at the content of American newspapers, especially on subject matter categories like politics, crime, and sports. Towards the end of the 1930s, Harold Lasswell, who was interested in the relationship between propaganda and public opinion in the 'new' mass medium of radio, used content analysis to investigate political values. During World War II, the U.S. government, through the Experimental Division for the Study of War-Time Communications under Lasswell, conducted the 'World attention survey' through a content analysis of major newspapers, which was designed to investigate newspaper coverage of foreign affairs. Others investigated the propaganda output from various organizations and individuals, focusing on aspects like the 'values' expressed in political speeches or the 'tone' of the headlines. Essentially, the origins of this approach developed in the study of the content of newspapers, but then evolved to be used as a way of evaluating political messages, especially Nazi and Soviet propaganda messages during World War II and the Cold War.

Much of this research was quantitative, relying on coding aspects of content into a number of discrete categories and counting their frequency. Later content analyses applied a similar methodology to television, but just about every type of media communication has been studied. Modern content analysis is still used for news content or detecting political bias, but it has also been used to investigate topics like gender representation in advertisements, violence in children's television programs, and representations of minority groups (for example, the work of the Glasgow Media Group in the United Kingdom on the news; and the research by George Gerbner and his associates in the United States on the Cultural Indicators project).

The first edition of the *Encyclopedia of language and linguistics* included an article on media language as part of the communicative process and outlined a different and more theoretically based tradition in the study of media language. It started with semiotics (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**) to demonstrate the need to think of media language as

part of a sign system or as a process of communication with complex social and cultural influences affecting the way in which media texts are produced and understood. The article reviewed the major approaches to the study of media language, such as critical linguistics, noting its approach to ideology and power in the representation of social reality, and its agenda in unmasking the seemingly objective nature of news reports; semiotics, especially as a way of decoding both verbal and visual aspects in advertisements; and discourse analysis, again primarily of news texts, but also phone-ins, interviews, and disc jockey monologues, with an emphasis on pragmatics, speech acts, and turn-taking. It noted a shift in emphasis away from textual analysis alone towards a more audience-focused approach.

Other overviews published more recently have outlined the research trajectories in language in the media through the work of individual linguists, especially with respect to the growing influence of Critical Discourse Analysis. Bell's (1995) overview maps out the approaches made in the study of media language and discourse from, first, Critical Linguistics and then Critical Discourse Analysis (CDA). He notes the growing importance of CDA and its sociopolitical concern to reveal inequalities of power as a standard approach to media texts, outlining the contributions of Fowler through his development of Critical Linguistics to apply functional grammar to news texts; of van Dijk's using text linguistics to develop discourse analysis to apply to news story structure; of Fairclough's bringing social theory, especially the work of Foucault, to discourse analysis, and to his contribution, along with that of van Dijk, to the development of Critical Discourse Analysis with its explicit sociopolitical stance. Bell's own work links text analysis of news stories to media production processes and the role of the audience. Critical discourse analysts are interested in both details of the text itself and the broader social, political, and cultural functions of media discourse to determine other layers of meaning. Much of their work to date has been on the analysis of factual genres like news rather than fiction or advertising.

CDA has become an important approach for studying media texts, especially in European linguistics and discourse studies.

However, to argue uniformity in the CDA approach could be misleading. The use of the individuals' contributions to structure overviews of the field is instructive here. CDA is not a holistic approach, using a single theory or even a single methodology. Its foundations are derived from classical rhetoric, pragmatics, text linguistics, sociolinguistics, and applied linguistics and reflect the growing interdisciplinarity in research between the humanities and the social sciences. Ideology and power underpin applications of CDA to issues relating to gender, class, and ethnicity and also to more general discussions about media discourses relating to politics or the economy (*see* **Media, Politics, and Discourse: Interactions**). However, depending on the discipline background of the researcher, the methodologies may differ, with both large empirical studies found as well as small, focused qualitative case studies. Weiss and Wodak's (2003) volume covers some of the research practices under the umbrella of CDA, and their introduction outlines some of the critiques and debates that have evolved with it.

The dominant paradigms of media language research have tended to produce critical evaluations of the power of the media to influence and even to subordinate their audiences. As indicated above, much of the work on media language, especially in critical linguistics and critical discourse analysis, has been undertaken on the news and is concerned with uncovering its underlying ideologies. In particular, this work targets for special attention social problems like discrimination and prejudice (for example, van Dijk's 1991 work on racism). The studies undertaken in CDA are designed with an emancipatory purpose; that is, they have a sociopolitical agenda intended to shed light on issues of power and domination. Thus, it should not be surprising to see so much CDA focused on the news.

News is not considered as some neutral image of the real world but as a product of news gathering and news making. In other words, news is the end result of a number of processes, including organizational policies and preferences that set the news agenda and selection and judgments about relative importance and significance. It is thus a representational discourse made by converting the raw data from a variety of sources, including eyewitness accounts, interviews, and media releases, into stories within the context of technical constraints like production deadlines, and in accordance with the news values of the time (*see* **News Language**; **Newspeak**). News values, or the set of criteria used to determine newsworthiness and hence whether or not an item is likely to appear as news, act as a filtering mechanism or gate-keeping device for what is reported.

The study of the news has always been at the forefront of media discourse research. The constructedness and selectivity of the news and its concentration on negative events, together with its connection to powerful institutions and commercial market imperatives, have proved compelling for language researchers, especially those who are interested in critical approaches to ideology, and have stimulated

investigations into story content, underlying values, and structure, as well as studies of representations of specific issues and groups. However, media language has been studied at other levels beyond journalistic practices, media production processes, and textual analysis.

The traditional distinction between news and entertainment has transferred into analytic approaches, with linguists and discourse analysts using conventional, language-focused, empirical methods on news texts, especially on news content, news values, and ideals of objectivity. This has left theorists from other fields like sociology, cultural studies, and women's studies to supply much of the insight into the entertainment side of media output. It is from these traditions that studies about consumption, popular taste, the politics of the everyday, and notions of pleasure and resistance have been undertaken.

A major contribution here has been insights from reception studies into reading practices and how readers or audiences negotiate meaning and respond to various media texts such as soap operas and women's magazines, as well as news programs. These are questions that usually lie outside traditional language or discourse analysis. Audience research has been the mainstay of media and cultural studies research for some years now as researchers endeavor to find out how audiences make sense of media texts. Reception studies have focused on specific genres to see how different social groups (based on age, class, ethnicity, or gender) or subcultures interpret texts in different ways. Hermes (1995), for example, in her analysis of women's magazines, draws heavily on responses from women who describe the pleasure they derive from reading what is often considered a devalued genre. Fewer studies have undertaken detailed linguistic analysis to relate textual features to audience interpretation. Richardson's work (1998) on economic reporting in television news is an exception here, as she links an analysis of media discourse on the economy with an analysis of the reception of that discourse.

Studying texts with images and sounds has presented challenges to conventional discourse analysis, which has valued modes of language through speech and/or writing over visual images or music. The mass media produce multimodal texts, that is, texts that draw from language, pictures, or other graphic elements and sounds in various combinations. Considerations of the multimodal nature of media texts are difficult to incorporate in language-based media analysis. Two examples of work on multimodality in the media, linked to linguistics, are Kress and van Leeuwen's work on text layouts (1998, 2001) and Cook's work (2001) on advertisements.

Kress and van Leeuwen have pointed out how the multimodality of the media needs to be taken into account when analyzing discourse. Their (1998) semiotic analysis of newspaper front page layouts shows how conventions related to the positioning of headlines, blocks of text, and photographs produce meaning and coherence; how visual cues (size, color, contrast) produce hierarchies of meaning; and how frames like lines and spaces produce separations or connections. They emphasize the importance of layout analysis in the critical study of newspaper language. The nature of advertising also means that analysts need to take account of pictorial and musical modes, even in advertisements where language predominates (*see* **Media: Semiotics**; **Visual Semiotics**; **Barthes, Roland (1915–1980)**). Cook (2001) stresses the links between language in advertising with the other modes and urges analysts to understand the interconnections they make with each other to construct meaning. In spite of the difficulties in trying capture such multimodality, concentrating on language and ignoring the other modes is to miss much of the potential for meaning of contemporary media texts.

Current Issues

The Impact of New Media

Researchers and other commentators have continued to be interested in media language and have expanded the field to include newer forms of media, mainly through attention to computer-mediated communication (CMC) (*see* **Language in Computer-Mediated Communication**). The development of global, digital, networked communication systems and their infrastructure in the latter part of the 20th century has captured the public imagination in terms of the seemingly limitless potential to provide access to information and to facilitate interaction with others. This has been greeted with either utopian predictions of a better informed and more democratic society with greater facilities to connect and interact with others through the creation of virtual communities, or a darker view of information overload, unregulated content, personal isolation, and even loss of ability to interact face-to-face, and a 'digital divide' between those with access and those without.

New on-line technologies have transformed news through the capacity to accumulate unlimited multimodal information in a single text and to permit different routes of access and different levels of interaction. On-line news departs from the constraints of space and time associated with print and broadcast news and instead organizes vast amounts of information content as self-supporting layers with hypertext

links (Lewis, 2003). In addition, various new forms of news have emerged with webcasts, web logs, news groups, and news alert services that provide constant access to news and embedded information.

Research on language use in computer-based media is struggling to keep pace with rapid technological innovations. The impact of the Internet and related technologies on language has been discussed (often negatively) in terms of language change and effects on literacy. Crystal's (2001) linguistic perspective offers evidence of the emergence of distinctive language varieties developing in Internet-related forms of communication, including e-mail, chat groups, virtual worlds (imaginary environments for text interactions), and the World Wide Web. In each, he notes adaptations in graphology, grammar, semantics, and discourse to suit the characteristics of the technology and its uses. Rather than forecasting the demise of the written form or, more dramatically, the death of languages as the result of the impact of new technologies, Crystal argues that the Internet is providing creative possibilities and enrichment opportunities for its users.

Work related to language in the new media has included studies on topics like web pages and hypertext links, e-mail discussion lists, and Internet video conferencing, and studies on themes like multilingualism in chat sites, the dominance (or not) of English in the new media, the extent of democracy, and the division between the information-rich and information-poor (for a range of studies, see Pemberton and Shurville, 2000; Herring, 1996; Jenkins and Thorburn, 2003; Aitchison and Lewis, 2003). Language research has focused primarily on computer-mediated communication via the Internet, its relationship to face-to-face communication, and its relative anonymity, as well as textual aspects like special language features and idiosyncratic codes of conduct and etiquette (or 'netiquette'). E-mail users and Internet chat users have developed spelling shortcuts like letter homophones or acronyms as a kind of coded shorthand to speed up typing (by saving keystrokes), and even special symbols created originally from ASCII characters ('emoticons' like smiley faces) to add emotional content. These shortcuts and symbols also help to differentiate regular users from newcomers. The so-called 'netspeak' or 'netlingo' has spread beyond CMC, with similar shortcuts and symbols adopted by mobile telephone users for text messaging, and CMC jargon like 'flaming' and 'spamming' becoming more widely used and understood.

Internet communication channels like chatrooms, bulletin boards, newsgroups, complex hyperlinked websites, and electronic games need to be thought of differently from traditional media texts (*see* **Language in Computer-Mediated Communication**). Such texts are characterized by their interactivity but also by their intertextuality, as they draw on other texts and play with established conventions of form and representation (Buckingham, 2000). In addition, many new media forms with their built-in potential for interactivity make the traditional distinction between author and reader (or producer and audience) less important, as texts are cooperatively produced and meanings are created, challenged, and changed. While it may be compelling to foreground the benefits of intertextuality and interactivity in contemporary media texts, especially in terms of creativity and innovation, many texts produced in new media are just refashioned conventional texts whose interactivity is based on limited choice and pathways.

Revisiting Traditional Media

The more traditional media continue to generate research interest with new insights (*see* **Radio: Language**; **Television: Language**; **Documentary**; **News Language**; **Sports Broadcasting**). Changes to the language of the media have been noted, such as growing tendencies for a more casual, conversational style with an increasing use of colloquial vocabulary and vernacular idiom by journalists and interviewers; a greater emphasis on celebrity; stress on the personal; and a marked trend to the short, sharp, sound bite designed to be pithy and provocative, especially when edited into news reports.

In debates about declining journalistic standards, the news media across a range of countries increasingly have been criticized for not separating news from entertainment, for personalizing and sensationalizing stories, and for focusing on 'softer' or 'lighter' stories rather than concentrating on more serious issues in a process termed 'tabloidization' (for international perspectives on tabloidization, see Sparks and Tulloch, 2000). Mass-market magazine content also has become more sensationalized with a growing emphasis on celebrity coverage, gossip, scandal, and intrigue. Franklin (1997: 4) has criticized both print and broadcast journalism, commenting that "the trivial has triumphed over the weighty; the intimate relationships of celebrities from soap operas, the world of sport or the royal family are judged more 'newsworthy' than the reporting of significant issues and events of international importance."

While news and public affairs remain an important part of media output, a significant portion of television output is devoted more directly to entertainment through soap operas, dramas, talk shows, reality

television, quiz shows, sports, and lifestyle programming (*see* **Television: Language**). It is likely that the increasing global trend of the media supplying more and more of these shows is underpinning the tendency for the news to become more conversationalized and more 'tabloid,' as it too comes under market pressure to entertain and to connect more closely with ordinary values and practices.

Research has continued as well on a range of variously disenfranchised groups, including women, children, the aged, ethnic minorities, and disabled groups (*see* **Media and Marginalized Groups**), and on moral panics, not just in the traditional sense of 'muggings' and escalating urban violence (Hall *et al.,* 1978) but in a more diverse sense that includes media coverage of issues related to pornography, pedophilia, health risks, and medical negligence (*see* **Media Panics**). Research also has been conducted into media's role in language development and literacy.

These new and continuing directions in research are contributing to the growing critique of the media and how they operate. Contemporary media language is changing, especially under the influence of globalizing technologies and changes to the media industries that are affecting the way our social world is presented to us. As global media corporations operate beyond the symbolic spheres of national influences and cultures, we are seeing increasingly globalized programming and convergent technologies, but whether this will translate into a homogenized culture with a global language is not at all certain. It is more likely that improvements in technology will give us more choice about where we get our information from and how we entertain ourselves.

What is evident within the study of language in the media is a continuing trend away from just text-based and/or purely linguistic approaches, not only in order to take account of factors surrounding media texts like the production processes, the characteristics of the medium, and the circumstances of audience reception but also to look at the nature of media language itself as it changes in relation to changing industry, social pressures, and emerging technologies.

Media and Marginalized Groups

How Do Media Marginalize Groups?

When the Nazi Party built their media outlets of print, radio, and cinema, they discovered the great benefit of producing constant propaganda about '*untermenschen*,' – the pillorying of 'lower people' on grounds of supposed racial and cultural differences – Jews, Slavs, Gypsies, Blacks, homosexuals, and people with impairments. The aim of this marginalization was to dehumanize their targets and gain public support for their exploitation of these groups, and then their extermination.

The media provide environments through which communication occurs. These environments are set within social, political, economic, and cultural parameters that reflect wider structures of power at the local, national, and international levels. 'Marginalization' is a process that reflects differentials in power and is expressed in unequal access to and representation in the media. Such marginalization can occur in any or all of the four analytical levels of the media: ownership and regulation, production and creativity, textual content, and audience consumption.

'Marginalized groups' can refer to any segment of a population with shared perceptions and experiences, who are unable to fully realize their rights as articulated in both the Human Rights and the Economic Social and Cultural Rights conventions of the United Nations. In particular, the term 'marginalized groups' refers to groups whose social or cultural characteristics generate opprobrium or hostility among other groups in society, so that their chances for a long life are significantly reduced.

This article examines the process through which marginalization occurs in the media, and gives some examples of resistance to such marginalization. Most research concentrates on the way the media relates to ethnic minorities, seeing them as the most obvious example of groups disempowered by communication structures in societies dominated by a single ethnic group, for instance, Whites in the United States, Anglo-Celts in Australia, or metropolitan Francophones in France. Studies of minorities and the media have been undertaken in most countries where there is ethnic diversity and has been a theme in the study of international communication. More recently, research on disability and the media has pointed to the significant role of stereotypes communicated by the mass media in disabling people with impairments.

Ownership

Most of the world's media are owned either by large multinational conglomerates (AOL Time Warner, Disney, General Electric, News Corporation, Viacom,

Media and Marginalized Groups

A Jakubowicz, University of Technology, Sydney, Australia

How Do Media Marginalize Groups?

When the Nazi Party built their media outlets of print, radio, and cinema, they discovered the great benefit of producing constant propaganda about '*untermenschen*,' – the pillorying of 'lower people' on grounds of supposed racial and cultural differences – Jews, Slavs, Gypsies, Blacks, homosexuals, and people with impairments. The aim of this marginalization was to dehumanize their targets and gain public support for their exploitation of these groups, and then their extermination.

The media provide environments through which communication occurs. These environments are set within social, political, economic, and cultural parameters that reflect wider structures of power at the local, national, and international levels. 'Marginalization' is a process that reflects differentials in power and is expressed in unequal access to and representation in the media. Such marginalization can occur in any or all of the four analytical levels of the media: ownership and regulation, production and creativity, textual content, and audience consumption.

'Marginalized groups' can refer to any segment of a population with shared perceptions and experiences, who are unable to fully realize their rights as articulated in both the Human Rights and the Economic Social and Cultural Rights conventions of the United Nations. In particular, the term 'marginalized groups' refers to groups whose social or cultural characteristics generate opprobrium or hostility among other groups in society, so that their chances for a long life are significantly reduced.

This article examines the process through which marginalization occurs in the media, and gives some examples of resistance to such marginalization. Most research concentrates on the way the media relates to ethnic minorities, seeing them as the most obvious example of groups disempowered by communication structures in societies dominated by a single ethnic group, for instance, Whites in the United States, Anglo-Celts in Australia, or metropolitan Francophones in France. Studies of minorities and the media have been undertaken in most countries where there is ethnic diversity and has been a theme in the study of international communication. More recently, research on disability and the media has pointed to the significant role of stereotypes communicated by the mass media in disabling people with impairments.

Ownership

Most of the world's media are owned either by large multinational conglomerates (AOL Time Warner, Disney, General Electric, News Corporation, Viacom,

Sony, Bertelsmann, AT&T and Liberty Media) (Shah, 2004) or by governments. While there are many additional smaller companies operating in national and local media markets, the large corporations set the broad tone and focus for media practices, especially in liberal democratic states with market economies. Most media markets are under some sort of control by the state, ranging from the almost total control exhibited in China and Cuba, through to the almost anarchic operation of the market in some post-Communist states. However, the dominant paradigm remains an environment where the print media are privately owned, and the electronic media are either private or have some government involvement. In the United Kingdom, Australia, and Canada, the government-run electronic media have a reputation for independence, taking seriously their role as defenders of the public interest. In the United States, public broadcasting has some support from the government, but is essentially a not-for-profit sector.

These patterns of ownership play an important part in how minority groups experience the media and use them to communicate within their own boundaries and with wider societies. Commercial media need to build an audience that they can 'deliver' to their advertisers, on whom their economic viability rests. Thus, they tend to search for 'demographics' that will be most attractive to advertisers, and who can be reached most efficiently. They seek out commonalities in audiences – language, culture, economic affluence – that they can use to expand their reach. Those people who are part of the majority group, particularly if it has greater economic and social power, will tend to find their interests and worldviews reflected in the media. On the other hand, minorities who are less powerful, and poorer, are less likely to find their interests addressed. One consequence of this exclusion has been the development of media targeting minority groups in their own languages and from within their cultures.

Government media may present a more wide-ranging view, depending on whether government polices seek to facilitate minority group inclusion, and the overcoming of marginalization, or the reinforcement of existing social hierarchies. Thus, government media may contribute to the demonizing of minorities who are perceived to be enemies of the state (and indeed commercial media may collaborate in such attacks).

With the development of the Internet and new media technologies in relation to print and broadcast, many countries have seen a rapid expansion of minority media outlets targeting particular communities. Global diasporas can thus maintain links across worlds, and cultural communities can build diversity within them, though at the real cost of separating different language communities from each other.

Regulation

Most countries have some form of media regulation, where governments establish rules under which they can operate. These rules can range from prescribing who can own media (for example; forbidding foreigners; banning political opponents; preventing monopolies; encouraging cultural diversity), to censorship, such as what can be printed or broadcast or uploaded to the World Wide Web. Many systems of regulations, including the self-regulatory codes of practice adopted by some media sectors, specifically prohibit discrimination against or the vilification of minority groups. In this they mirror the UN ESC Rights convention, and its signatories' commitment to implement those rights "without discrimination of any kind as to race, color, sex, language, religion, political or other opinion, national or social origin, property, birth or other status" (United Nations, 1966/1976: Article 2: 2).

The rise of racism on the Internet has become a particular focus of government attention in Europe. The European community has undertaken a series of studies through the European Monitoring Centre on Racism and Xenophobia (EUMC) that has sought to document the expansion of hate speech on the Internet, and then to develop strategies of how to resist its impact on vulnerable communities. While some countries have specific legislation under which hate speech on the Internet is a criminal offense, others have preferred to develop avenues for civil recourse or have argued that free speech rights should not be restrained on the Internet.

Indeed, the regulation of hate speech altogether has become a matter of significant controversy in many countries, especially where the issues have arisen from religious differences. Studies of anti-Semitism have shown how complex contemporary debates over the Israeli-Palestinian conflict have intensified this already emotionally charged arena, while Arab and Muslim groups in Western countries have pointed to the need for restrictions on the demonizing of Arabs and Muslims in the media.

Thus, national regulatory regimes increasingly have to respond to some of the dynamics of marginalizing, trying to balance the values of open discussion and debate with the dangers of humiliation of minority groups whose participation in society can be heavily compromised by hate speech. Regulation becomes important in terms of the process of media production, and how messages are generated and transmitted.

Production

If communication is a process through which meaning is conveyed from a point of production to a point of consumption, then meanings are first constructed by media professionals that choose elements to form into narratives. The production locus is always one of choice; the producers select from a range of possibilities and build an argument, story, or experience that they believe will move their audiences in some way. Whether it is journalism, fiction, advertising or nonfiction, television game shows, or 'reality TV,' there are creative minds building conceptions of how the audience would be moved – emotionally, viscerally, and intellectually. Communication is always about change – changing how people are before they experience it – and trusting or hoping that the desired effect will result.

Studies of newsrooms have shown how the dynamics of news reporting are influenced by the ethnic makeup of the reporters. In societies where aboriginal communities survive, research demonstrates that few aborigines are involved in media production, and their stories are underrepresented in the media. Similarly, immigrant and second-generation populations are underrepresented in news media organizations, while people with impairments are almost totally excluded. In racially diverse societies (e.g., France, the United States, the UK) this diversity, to some extent, may be reflected through the range of media, but is rarely reflected within the dominant media organizations. Despite some moves towards affirmative action, the tendency of powerful positions being held by powerful men from the dominant community remains.

These production structures have tended to reinforce existing practices and worldviews. Even where minorities exist in significant numbers in local communities, American researchers have shown that this has only marginal effect on content and employment. Where economic hierarchies mimic racial ones, the media production forms reflect both economic and racial inequalities, and, to some extent, sustain and reinforce them. Thus there may be no intentional vilification of minorities, yet their continuing marginalizationmay be a consequence of their historic exclusion and the worldviews in the organizations that control the communication system.

It requires a conscious self-awareness by media proprietors of the consequences of their actions – many of which are unintended – to begin to remedy such continuing inequities. There are many examples of managers deciding to change the organizational culture of exclusion – recruitment campaigns for minority employees, active dialogue with excluded communities, strategies to widen audience appeal by diversifying content, and the sustained selection of minority community members as expert commentators (and not just on minority affairs' issues).

Disability communities have also sought to modify stereotypes and marginalization. Some media have included people with disabilities in their normal lineup, with British broadcasting organizations in 2004 pledging their commitment to raise disabled involvement in production. However, disability remains a significant area where marginalization continues.

Some advertisers have also seen the importance of normalizing disability. In the United States and Europe, people with impairments are appearing more regularly on TV screens, and the 'access' movement, seeking to ensure the disability-friendliness of the Web, has been increasingly successful in generating and disseminating accessibility standards.

Content

Given the range and diversity of media outlets, it could be argued that every community of language or interest can find a forum for communication, particularly in larger and wealthier societies. This view carries with it a serious implication: the communication networks that enable societies to function as integrated units may be in the process of unfurling – rendering them more like places in which multiple diasporic communities cohabit in their own communication spaces.

The complexity of 'mediascapes' carry embedded within them 'ethnoscapes,' or visions of the world as perceived through the eyes of particular ethnic collectivities. Dominant media tend to sustain the views of the dominant communities, so that the content of these media tends to privilege the interests and concerns of these groups.

Studies of stereotyping of minorities – Jews, Blacks, disabled people, Muslims – have shown that these groups tend to be framed by the perspectives of able-bodied White Christians. The stereotypes tend to speak to the fears and threats these marginalized groups are felt to represent. Thus, Jews were often portrayed in Euro-American media as outsiders who carried particular cultural attributes as a group, sometimes positive, sometimes negative. In recent years, Jews have again been represented in harsher terms in Arab media. African-Americans were typically represented in the past in American media as criminals, comics, or sports people, though some have emerged into the front rank of Hollywood actors. Still, for the most part, stories about Blacks in dominant culture media neither canvas the range of Black experiences, nor explore issues relevant to

Black people in any depth or from their point of view. Such stereotypical practices have two effects: They exclude Black people from the communication community formed by specific media, and they transmit biased and limited information to other participants in those communication communities. Such miscommunication serves to further marginalize Blacks from the collective discourse of the society, and thus both reinforces their alienation and legitimates wider practices of social exclusion. In the United States, there has been a major increase in Black (and Hispanic) cable television channels, and a turning away by these audiences from 'mainstream' channels.

Over recent decades, and especially since the events of September 11, 2001, Arabs, Muslims, and other people from the Middle East and South Asia have experienced the full force of stereotype and hostility in Western media, while the media in their countries of origin have tended to emphasize the most oppressive aspects of the imperial histories of Western cultures. Many Arab and Muslim organizations have developed strategies to influence media content in Western countries, through media training of spokespeople, the development of media monitoring projects, and the use of complaints mechanisms.

Textual studies have demonstrated the processes through which discourses of marginalization are sustained. News programming, for instance, will frame stories within the context of expected protagonists and antagonists. In societies with racialized histories, the discourses mobilized in the media may tend to legitimate preexisting hierarchies of a certain race, while reinforcing prejudices against immigrants from minority backgrounds. Disability may be used as a metaphor for evil, so that fear of people with impairments is reinforced and their social exclusion intensified.

Advertising carries some of the most important content, through its constant messages about appropriate social behavior. Television has become one of the most important socialization agents for children in advanced Western societies, with children in the United States watching on average about twenty hours per week; in a year they may see up to 200 000 commercials. Children learn a great deal from this experience about race and disability, their own racial groups and others, and about what it means to be normal. Biased, negative, or minimal representation of minority groups can intensify social exclusion directed against them, and undermine their own feelings of self-worth and personal capacity.

Audience/Consumption

Meaning is realized by audiences by their working on texts. While producers propose ways that texts should be interpreted, usually privileging one interpretation, the meaning (i.e., the reinforcement or changes in perception, perspective, or behavior among audiences) is not totally determined by the intent of the authors. While meanings are individually experienced, they are socially constituted through the shared communal discourses developed over time within subcultures.

The rise of mass media during the 20th century was predicated on the creation of undifferentiated audiences, and pushed towards homogenized lifestyles expressed because of the growth of large organizations and the suburbanization of metropolises. Over the past three decades, and accelerating in this century, technological change and social diversification have undermined the reality of mass society, generating in its place a more variegated, urbanized, and older population. Most Western societies are characterized by an ageing dominant population group with low birth rates, while their minority groups tend to be younger and have higher birth rates.

These demographic changes have already seen major audience shifts for the US media and similar transformations are likely for other societies with immigrant and refugee populations. By 2050, the non-Hispanic White population of the United States will have declined to about five in ten, a decrease from about seven in ten in 2000. In the meantime, the African-American population will have risen slightly from 13 to 15%, with Asian and Pacific Islanders rising nearly 300% to one in twelve, and Hispanics growing from one in nine, to one in four. One major effect of these changes is that the child and youth media market will be dominated by minorities. Those who are currently marginalized by the mainstream will have become together almost half the population, and much more than half the youth population.

Audiences seek reinforcement from their media experiences. They look for cultural experiences that confirm their identities, and validate their expectations and desires. Where there is choice, and they experience marginalization or exclusion, they will turn towards media that satisfy their needs and address their realities. Increasingly wealthier and more educated populations are turning to the Internet for their information needs, selecting services that suit them. Internet providers talk of building user communities who both draw on the materials provided to them but also interact with other users of the same services. As communities of interest develop, communities of place become less important, and the discursive environments used can become global rather than local. Audiences for any one source become smaller, even

though demand for information and entertainment continues to expand.

US studies of children as audiences have shown that they would welcome a more diverse range of representations of people in their television viewing. Studies of minority audiences in Europe, Canada, and Australia also demonstrate their desire for a better representation of their own stories and experiences in mainstream media. Many express their frustration with the repetition of tired stereotypes and also their clear sense of the peripheral nature of their participation in society as it is expressed in dominant group media.

Alternatives

Many of these issues have been recognized by government, community, and corporate bodies; they have developed a variety of strategies that have started to remedy the exclusion and marginalization of ethnic and disabled communities. Technological change (e.g., digital broadcasting, satellite newspaper transmission, the Internet, cable television) has facilitated the development of alternative media outlets which provide opportunities for communities to hear their own voices or read their own stories (although with only minor impact outside the community boundaries).

Within the mainstream media in the United States, Canada, and the UK, there have been programs to implement affirmative action, with the active recruitment of minority staff as journalists, writers, producers, and directors. Similar approaches have recently been extended to cover people with disabilities, with a cross-Europe initiative emerging in 2003.

However, European studies have shown that the challenge continues for the media to talk 'with' rather than 'about' minorities, indicating that there is still a pressing need to enhance equal representation by giving voice to ethnic, cultural, and religious minority sources, and by involving those affected by discrimination in the media. Minority perspectives need to be covered in the mainstream media, not only on issues that concern the ethnic minorities, but also in other general news genres. Governments need to convince media professionals of the necessity to integrate immigrants' points of view in their productions more widely, and not only in productions dealing with minority issues.

The media can contribute to societal integration and cohesion, by reflecting diversity, and giving voice to groups that have something to say about issues concerning them and society as a whole, whether they are marginalized for their culture, language, disability status, or religion. The processes of marginalization occur at all levels of the media and need therefore to be addressed systematically.

Media Panics

J Leach, University of Queensland, Brisbane, QLD, Australia

© 2006 Elsevier Ltd. All rights reserved.

Cultural panics have existed as long as culture itself. Herodotus reports that the citizens of Asia Minor panicked when rumors that their wells had been poisoned by the Greeks surfaced in the 7th century B.C.E. The rise of the mass media from the 17th century onward, however, meant that panics could be monitored, contained, and most importantly, created by the media itself. In the 20th century, the introduction of social statistics and the ever-increasing amount of scientific information available for public scrutiny encouraged moral panics over increasing crime, environmental degradation, changing social norms of gender and sexuality, and a host of health-related issues. Strikingly, these panics frequently tell us more about the structure and power of the media than they do about the issue supposedly causing panic. The model of a media panic discussed below owes much to theories of social panic and there are some limitations to seeing media interventions in social problems in these terms. After considering the elements of media panics, there is a discussion of the limits of the model.

Media panics usually start in the news. Broadsheet newspapers, television news, radio news sources, tabloids, and Internet news sources describe periodic or new phenomena as systemic disorders that are worthy of sustained audience and media attention and needing some sort of urgent intervention. As such, reports of phenomena such as crime statistics articulate to traditional news values. Most crucially, to be news it must be 'new.' However, crime is not a new phenomenon and crime statistics are analyzed periodically. The 'newness' of the statistics in combination with typical media claims that crime is 'getting worse' creates a message of a systemic social disorder. Adding to the gravity of this message, the claim that there is a 'systemic disorder' produces a contradiction between our knowledge of crime as a persistent phenomenon and the claim to its newness. To resolve this contradiction, new categories of crime or deviance are created and audiences are morally sensitized to these new forms of crime; in short, new categories are created for audiences to worry about. In addition, the media, needing to direct and hold audience attention, selectively engage events in order to show their most extraordinary, most worrisome, or otherwise unique features. Thus, violent crimes, bank robberies, and 'moral deviance' receive more news attention than white-collar crime or domestic violence. Reports of extraordinary or worrisome events are usually coupled with a generalized claim that these remarkable events 'could affect you.' This conforms to the news value that news events should be audience relevant. The contradictory messages produced by claiming both the remarkable and the everyday can lead to audience confusion, apprehension, annoyance, and alleged social and moral panic.

The structural features of a 'media panic' include a news item and statistics or narratives that support the

Media Panics

J Leach, University of Queensland, Brisbane, QLD, Australia

Cultural panics have existed as long as culture itself. Herodotus reports that the citizens of Asia Minor panicked when rumors that their wells had been poisoned by the Greeks surfaced in the 7th century B.C.E. The rise of the mass media from the 17th century onward, however, meant that panics could be monitored, contained, and most importantly, created by the media itself. In the 20th century, the introduction of social statistics and the ever-increasing amount of scientific information available for public scrutiny encouraged moral panics over increasing crime, environmental degradation, changing social norms of gender and sexuality, and a host of health-related issues. Strikingly, these panics frequently tell us more about the structure and power of the media than they do about the issue supposedly causing panic. The model of a media panic discussed below owes much to theories of social panic and there are some limitations to seeing media interventions in social problems in these terms. After considering the elements of media panics, there is a discussion of the limits of the model.

Media panics usually start in the news. Broadsheet newspapers, television news, radio news sources, tabloids, and Internet news sources describe periodic or new phenomena as systemic disorders that are worthy of sustained audience and media attention and needing some sort of urgent intervention. As such, reports of phenomena such as crime statistics articulate to traditional news values. Most crucially, to be news it must be 'new.' However, crime is not a new phenomenon and crime statistics are analyzed periodically. The 'newness' of the statistics in combination with typical media claims that crime is 'getting worse' creates a message of a systemic social disorder. Adding to the gravity of this message, the claim that there is a 'systemic disorder' produces a contradiction between our knowledge of crime as a persistent phenomenon and the claim to its newness. To resolve this contradiction, new categories of crime or deviance are created and audiences are morally sensitized to these new forms of crime; in short, new categories are created for audiences to worry about. In addition, the media, needing to direct and hold audience attention, selectively engage events in order to show their most extraordinary, most worrisome, or otherwise unique features. Thus, violent crimes, bank robberies, and 'moral deviance' receive more news attention than white-collar crime or domestic violence. Reports of extraordinary or worrisome events are usually coupled with a generalized claim that these remarkable events 'could affect you.' This conforms to the news value that news events should be audience relevant. The contradictory messages produced by claiming both the remarkable and the everyday can lead to audience confusion, apprehension, annoyance, and alleged social and moral panic.

The structural features of a 'media panic' include a news item and statistics or narratives that support the

claim that this news item is relevant, even worthy of urgent attention, for general audiences. This news item must then be articulated to other issues of public concern or labeled extraordinary and construed as deviant and needing public scrutiny or action. The 'panic' of a media panic emerges from a series of contradictions about newness, newsworthiness, relevance, and deviance. And finally, the audience should not be left in a state of panic or anxiety. Socially sanctioned experts typically express a range of options, again, in the media, for audiences to intervene in the issue. This might include the media source exhorting audiences to 'be aware,' seek out more information,' 'call their local politician,' or even to buy a certain product to reduce confusion or panic. The ultimate intervention in media-generated panics is legislative change by political, policy, or judicial systems against social actors that have been labeled as deviant or part of the problem.

The events that cause media panic are rarely 'made up' or entirely fictional. Rather, the media directs attention to phenomena and links these phenomena with troubling public issues or labels certain social actors as 'deviant' and thus worthy of public scrutiny and intervention. The global HIV/AIDS pandemic provides a striking example. The emergence of the disease worldwide is an actual event that has killed over 14 million people. The media, drawing attention to the unknown cause of the disease and its debilitating and wasting effects, made the case that HIV/AIDS was worthy of audience attention. Coupled with statistical evidence that the death toll was rising and the disease was associated with sexual practices and drug use that the media deemed deviant, the disease received more press than other emerging pandemics such as tuberculosis. The ensuing panic was both 'moral' and media generated. Deviance was created in relation to the disease and activists and educators have had to work against this initial media-generated definition. The crucial issue is not that the HIV/AIDS pandemic is not real or serious; the issue is that the media focus attention and create worry about particular aspects of the pandemic with moral overtones. Thus, 'media panic' about HIV/AIDS sanctioned homophobia and a distrust of certain immigrant groups. The appropriate intervention, given this framing of the issue, is avoidance and suspicion of particular social groups. The significance of media panics demonstrates the power of the media in agenda setting and framing social issues.

The use of statistical and scientific evidence, as well as scientific and medical expertise, has become increasingly important to media sources and plays a larger role in media panics. Drug panics, for example, are recurrent in the media as different recreational drugs, from cocaine to ecstasy to 'chroming' (sniffing fumes from paints) are introduced to audiences and their effects are discussed by experts. While experts in the recent past have included politicians, stakeholders, religious leaders, and other 'right-minded' figures, medical or health-related issues are frequently dissected by physicians or experts with academic or professional scientific qualifications. This adds another level of media engagement with audiences. Not only do audiences need to **do** something urgently, there is also more that they need to **know**. That knowledge can also come from experts introduced in the media. In the drug panic example, concerned parents might be alerted to a new threat by a news story. This may be followed up by a news magazine program where doctors and scientists discuss the possible physiological effects of drug use and the concurrent social behaviors parents might observe in drug-taking children. In addition, there might be statistical evidence of 'at-risk' populations and experts to comment on ways of lowering that risk. There also might be experts to advise parents on the best strategies of intervention. While this all works to raise and not lower anxiety, there becomes a wide body of expert knowledge that is needed before the audience – here parents – can take action. There are contradictions here also. Experts frequently disagree on the causes and risks of social behaviors and even on the results of scientific studies. Audiences knowing more, then, becomes a difficult proposition among a range of opinions, interpretations, and ambiguities. This can further support the role of the media as audiences look for clarification or it can turn audiences away as they throw their hands up in the face of so much conflicting information. It is clear, however, that the rise of expert culture has perpetuated and supported a number of media panics.

The rise of global media systems marks an unprecedented centralization of media attention and the potential to create 'panics' in large audiences. News sources can focus mass audience attention in more precise ways and create concerns that run across national boundaries. Creating concern or 'panic' works in the media's interest as concerned audiences are consistent viewers and consistent viewers help media companies sell advertising. Panic is good for the media system; often the media will even attempt to create panic about the possibility of media panics, raising concern about the media's own ability to raise concern. Media panics are also useful for the state insofar as deviance can be defined and 'rooted out' or 'policed' by concerned members of the public, thus creating an opportunity for audiences to feel empowered even when the terms of that empowerment are defined in the media. Media panics may also reflect a

trend in dominant cultures to be concerned with their own plight. In this way, media panics are symptoms of a larger crisis of a 'risk society.' On this account, the various plague, crime, and moral downfall scenarios being circulated in media systems cause panic as a culture becomes increasingly aware of its potential for self-annihilation through nuclear war, environmental degradation, social exclusion, and pandemics of disease.

However, the model described above points out certain features of media panic and ignores others. As the issues raised are not fictional, what would proper media treatment of important social issues look like? How would they properly emerge in a way not to cause panic? The features outlined above also give the impression that media panics follow a formal road map. In actuality, they differ substantially; the origins and resolution of HIV/AIDS panics around issues of sexual orientation only bear some resemblance to the issues of class and race that motivated drug panics. Finally, the term 'moral panic' itself has been used to political ends in the media. At the end of the 1990s, sex abuse scandals within the clergy were making worldwide headlines. Members of the clergy defended themselves by accusing themedia of creating panics, thus attempting to diffuse audience attention and interest. This last feature of 'media panics,' the ability of the media to create panic and by that very act, be open to the criticism of causing undue panic, demonstrates both the power of the media to control social agendas and the power of audiences to resist and restructure media agendas.

Media texts are frequently being used as corpora in linguistic analysis, treating politics- and policy-related questions such as social inclusion and exclusion, stereotypes, and constructions of national or ethnic identities (Wodak and Busch, 2004). For instance, over 40% of the papers published in the journal *Discourse & Society* are based on media texts (Garrett and Bell, 1998: 6). There are different reasons for this: given their public nature, media texts are easily available and accessible, offering even a historic dimension through archives. Media texts can be assumed to have an impact as they address and reach multipliers or a more general large public. It can be assumed that they receive attention by their audiences, as their reception is voluntary. Media texts, as other texts in the public domain, provide discursive and linguistic resources that can be seen as authoritative voice (Bourdieu, 1982). Although also in media studies news is one of the most widely studied media forms, the connection between

trend in dominant cultures to be concerned with their own plight. In this way, media panics are symptoms of a larger crisis of a 'risk society.' Media texts are frequently being used as corpora in linguistic analysis, treating politics- and policy-related questions such as social inclusion and exclusion, stereotypes, and constructions of national or ethnic identities (Wodak and Busch, 2004). For instance, over 40% of the papers published in the journal *Discourse & Society* are based on media texts (Garrett and Bell, 1998: 6). There are different reasons for this: given their public nature, media texts are easily available and accessible, offering even a historic dimension through archives. Media texts can be assumed to have an impact as they address and reach multipliers or a more general large public. It can be assumed that they receive attention by their audiences, as their reception is voluntary. Media texts, as other texts in the public domain, provide discursive and linguistic resources that can be seen as authoritative voice (Bourdieu, 1982). Although also in media studies news is one of the most widely studied media forms, the connection between

media and politics has not been sufficiently investigated (Fiske, 1987: 281), and no coherent theory that integrates media theories, political theory, and social change has been developed so far.

The first part of this article discusses the correlations between media and politics. The historical perspective on developments in Western Europe shows a change of paradigms that becomes visible in the media order, in conceptions of the public sphere, and in media theory more generally. The second part focuses on approaches to the analysis of political discourse in the media. Given that the political field and the media field both undergo a process of rapid change, a flexible framework is needed, which is not based on fixed categories such as ownership or media genre and which establishes close connection between media texts and contexts of production and reception. The article therefore foregrounds approaches developed within critical discourse analysis (CDA).

Media, Politics, and the Public Sphere

The post-World War II media order in Western Europe was characterized by a strong public service broadcasting sector that aimed at reinforcing a unified national public sphere and was therefore protected by broadcasting monopolies. While print media were differentiated according to ideological, class, regional, and language criteria and therefore reached only segments of the national public sphere, the public broadcasting service addressed the nation as a whole. The public service saw itself as a kind of classroom for the nation, which it served, represented and constituted. National broadcasting could create "a sense of unity – and of corresponding boundaries around the nation," "turn previously exclusive social events into mass experiences," and "link the national public into the private lives of citizens" (Morley, 2000: 107). Within the public service the state language was seen as a means of strengthening national identities. In the case of multilingual states, such as Switzerland or Belgium, this led to the creation of parallel systems in the respective languages within the national broadcasting order. Imagining the audience as a national community and structuring communication in a unidirectional paternalistic top-down manner also determined language practices that emphasized the cultivation of a 'pure' standard language. This became apparent not only in language practices excluding 'deviant' accents, but also in ideologically loaded metalinguistic discourses.

Early mainstream theories in media sociology were based on the political philosophy of Enlightenment and viewed the individual as an actor in fulfilling the social contract that grounds civil society. The ideal of media as the fourth realm, as an autonomous controlling institution, which faces the legislative, the executive, and the judiciary, presupposes that there is a relationship of autonomy and distance between the media and the political sector. Such approaches to media and politics tend to conceive media as an omnipotent manipulatory force or to relativize the power of media with respect to politics. In both, communication is conceived as a linear process, in which the transfer of meaning from the sender to the receiver is the central concern. Such approaches fail to locate media, individual actors, and audiences within conflicting fields of interest and power relationships, which are in turn constitutive for the formulation of subject positions (Mattelart, 1999: 94).

Habermas's discourse-based concept of the public sphere defines public sphere as the mediating institution between society and the state. Media fulfill a dual role; on the one hand they are a commodity depending on the rules of the media and the advertising market; on the other they structure social relationships. In the first phase of the constitution of bourgeois nation states, media contributed to the development of the public sphere, whereas in a later phase – because of commercialization and the intimate linkage between the state and the economy – they contributed to its erosion. Habermas's model, originally published in 1962, was based on the assumption of a single unified (national) public sphere. Critics of Habermas's model were formulated by feminist studies (e.g., Young, 1987) and later also by scholars addressing the question of minority exclusion (e.g., Morley, 2000; Husband, 2001) or language as a factor of such exclusion (Busch, 2004). Habermas (1990) himself revised his model and conceded that he had neglected the existence of counter discourses, counter publics, and counter cultures. Drawing upon Foucault's notion of discourse, he recognized that the exclusion of the 'other' is a constitutive element in the formation of the public sphere and that the formation of dominant discourses is based on mechanisms of exclusion. Nevertheless, suppressed discourses can have a transformative impact on dominant discourses.

Struggle of Discourses

In the 1960s and 1970s, various processes of differentiation transformed the media landscape. All over Europe, media became a central topic on the political agenda. The state monopoly on broadcasting as well as the commercial media trusts that gained power in the concentration process were criticized for excluding a range of social groups and deviant political positions. In other words, social movements claimed

an adequate representation within the national media systems. To achieve this aim, social movements largely had to rely on their own media such as posters, leaflets, and alternative print media to express alternative or counter opinions in public.

At the same time, public service broadcasting differentiated its programs according to different styles and tastes. Alongside the nationwide programs, specific regional programs gained in importance. On the political level, regionalization in the media corresponded to a revalorization of regional autonomy and of regional languages. The idea of cultural homogeneity conceived as masculine, white, and monolingual lost in impact, as counter discourses challenged the dominant views and hegemonic social relations.

The main challenge for the public service media stemmed from the pressure of private media enterprises. It was the opposition of public versus private that dominated media policies and finally led to the abolishment of broadcasting monopolies in Western Europe. So-called liberalization first only concerned radio, which had abandoned its function as the leading medium to television already in the 1960s. In commercial media, the information aspect became subordinated to the entertainment component.

Technology-driven media theories, which prioritize aspects of form and format over aspects of content, attribute to the medium as such the leading role in shaping and transmitting a message. This approach became popular with McLuhan's succinct formula "the medium is the message," which marks a break from concepts that ascribe a preeminent power in influencing public opinion to media, both in an educational and in a manipulative way. It neglects, however, the question of how technological developments are appropriated socially and culturally. Discourse-oriented approaches to society and politics as developed by Habermas, Foucault, or Bourdieu have a strong impact on media studies and theories. This shift of perspective emphasizes social relations and cultural factors and allows revealing hegemonies and power relationships. In this sense, media can be seen as sites of discourse struggles.

Fragmentation and Reconfiguration of Media Spaces

In the 1990s, the process of decentering the national public sphere gained in momentum. The availability of satellite and cable TV and later of the Internet has led to a further fragmentation of media audiences, a reconfiguration of media spaces and an increasing multidirectionality of communication flows. Two distinctive developments characterize the new kinds of transnational broadcasting spaces and new transnational configurations of culture: the emergence of global broadcasting regions which link populations of neighboring countries on the basis of proximity, common cultural heritage, language, or ethnic identity, and the creation of new diasporic broadcasting spaces, which gather into a single audience different national communities scattered across the world (Robins, 1997: 15–16). In the broadcasting sector, the media landscape becomes complex and manifold. In addition to the traditional national public service emerge not only the global players, but also a range of local media that themselves tend to have various translocal and transborder connections. While commercial interests are constructing a transnational space as a by-product of their primarily economic motives, nonprofit ventures seek to empower local communities, marginalized populations, and civic activists.

Media formats and genres developed by public service media change in nature. Genres and text categories that used to be separated are blurred, new genres appear (e.g., infotainment, edutainment, reality soaps). Political discourse is not confined to the information genre, but also has its impact in the entertainment sector.

This development in the media field corresponds to a decentering of the nation–state at the political level. Under the pressure of an increasingly globalized economy, the state gradually loses its central role as an organizing principle in society and delegates former core competencies, on the one hand, to institutions and expert committees on a supra-state level, and on the other, to a substate level of regions and communes as well as private bodies or NGOs (Castells, 2003). Neoliberal discourses are replacing the former vision of the welfare state. The deregulation of the media system and the weakening of state influence on the media order potentially provide the media with more space for acting in their own right.

In the current debate on the desideratum of a European public sphere, it becomes obvious that the nation state with its public arena is not withering away yet. At the same time, shortcomings already inherent to the notion of a national public sphere – exclusions and fragmentations – are becoming more accentuated. Husband (2001) draws attention to the necessity of reflecting on possible interfaces between parallel and mutually exclusive public spheres in order to guarantee some social coherence. Whereas political discourse could easily be tied to (national) discourse communities within the nation state paradigm, it seems to be becoming more multilayered now.

Approaches to the Analysis of Political Discourse in the Media

In the academic field, certain assumptions that were taken for granted within the nation–state paradigm are increasingly submitted to revision. In retrospective, media are acknowledged a central role in the formation of the modern nation–state as well as in the standardization and homogenization of national languages. Present media developments seem to also allow more space, however, for nonstandard linguistic practices, for multilinguality and multivoicedness (Busch, 2004).

The present trend in approaches to media texts can be characterized in both disciplines, in media studies as well as in linguistics, by a focus away from text-internal readings, where readers are theorized as decoders of fixed meanings, to more dynamic models, where meanings are negotiated by actively participating readers. Consequently, there is a stronger emphasis on processes of transformation of discourses, on recontextualization, and on intertextuality. Nevertheless, studies that focus on production-related transformations are still scarce. Although since Stuart Hall's (1980) influential model of decoding and encoding, the reader is attributed an active role in the constitution of meanings, studies that combine the moment of the media text and its reception are not very common.

Rapid changes within the media system and within the political order demand an analytical framework for the study of political discourse in the media that is flexible and sufficiently open. Critical discourse analysis (CDA) provides such a framework, as it combines in an interdisciplinary approach close textual analysis with the analysis of the larger social context as well as with routines of textual production and reception. CDA foregrounds a dual focus in the approach to political discourse in the media: the detailed analysis of communicative events and the order of discourses, i.e., to locate these communicative events "within the fields of social practice and in relation to the social and cultural forces which shape and transform those fields" (Fairclough, 1998: 143). This involves the analysis of texts, of discursive practices of text production, distribution, and consumption, and the analysis of social and cultural practices that frame discourse practices and texts (Fairclough, 1998: 144).

The Field of Politics and of the Media

To capture how the political and the media domain are articulated and how media discourses and political discourses are interlinked, it is useful to draw upon the notion of different fields that characterize modern society as developed by Pierre Bourdieu (1982). According to Bourdieu, the separate fields of the economy, the state, the legal system, the arts, politics or the media, etc. are each marked by their own particular form of institutionalization and by their own social and discursive practices. The political field has undergone significant changes that led to an increasing specialization and professionalization of the involved actors. Political discourse manifests itself among others in parliamentary debates, political meetings, party conferences, and public debates. A certain amount of political discourse is designed from the outset to be reported and represented in the media. This is, for example, the case for parliamentary speeches in which politicians often do not only address the assembly but also a larger general public, as they anticipate mediatization. Referring to the field of politics, Bourdieu suggests that political discourse is doubly determined, on the one hand internally within the field of professional politics and on the other externally, i.e., in relation to the people politicians represent as well as in relation to other fields, the media field being one of them.

The field of journalism and the field of the media are determined by power relations and competition between different media, which become visible through certain indicators such as the market share, the value on the advertising market, the symbolic capital of prestigious journalists. The importance of the media field in relation to other fields, such as the field of politics, is that it holds a sort of monopoly on the means of production and on large-scale distribution of information. Political discourse and action are subjected to the principle of selection exerted by journalists and the media within the logic of the journalistic field, which is in turn dominated by market competition (Bourdieu, 1996: 45ff). In order to escape possible censorship that results from the selection process in media production, political actors develop strategies of presenting their concerns in forms that are likely to become media events or stories with news value. Political actors adapt their agenda and style to the requirements of media presence (e.g., short statements, studied gestures, hairstyle) and of media formats (live debates, talk shows).

Both fields, the political and the journalistic, have in common that they are directly under the influence of the sanctions of the market and of plebiscite. According to Bourdieu (1996: 92), the linkage between the two fields amplifies the tendencies of the agents involved in the political field to act according to pressures exerted by the expectations of a mass public and reduces the autonomy of the political field. In the media field, competition between different media enterprises has

become more accentuated in the past few years. Since the fall of the state monopolies, the public service broadcasting cultures have also changed significantly. Even genres that used to be relatively stable such as the national news programs on television have experienced fundamental transformations. For instance, there seems to be an acceleration of pace, a compression of time, in which live-broadcast is given priority over in-depth investigation, and short and diversified news items are combined into a more or less connected rapid succession of news flashes.

From the perspective of CDA, the relationship between the field of politics and the field of media can be understood and analyzed as a chain of recontextualizations. Writing or speaking about any social practice is already an act of recontextualization (Caldas-Coulthard, 2003: 276). Recontextualization can involve suppression and filtering of meaning potentials, but it can also result in expanding meaning potentials by adding or elaborating upon the an earlier version of the text (Chouliaraki and Fairclough, 1999). Van Leeuwen and Wodak (1999: 96) suggest that transformations due to the recontextualization of political discourse include deletion, rearrangement (e.g., changing the order of propositions, altering emphasis), substitution (through linguistic means such as nominalization, metaphor, metonymy, synecdoche, personalization), and addition (adding new elements to the representation of social practices). In this sense, recontextualization can in turn have a transformative effect on a particular practice or create a new practice.

Linking the fields of politics and media, recontextualization takes place in two directions: media recontextualize political discourse (e.g., speeches) and politicians recontextualize political discourse derived from media (e.g., quoting media as public opinion, as the voice of the common man in the street).

In the process of recontextualization, discourses may also be transposed to a more legitimate context (e.g., from an informal context to the more formal of parliamentary speech) and thus gain in power and status. Legitimation of a text can also be gained through reference to authority, reification, moral evaluation, or through reference to "true stories from real life." Authority can be gained through reference to law, a person with recognized authority, or an institution. On the other hand, laws in democratic societies often emerge from chains of political discourses in which media have their place (Wodak, 2000).

Analyzing Media Texts

With the rapid and dramatic changes in the media sector, obvious categorizations of media with regards to their area of dissemination (national, local, international, etc.), ownership structures (public service, private), or orientation (information, entertainment, education) are becoming more and more difficult. The formerly propagated separation between information and entertainment/edification can hardly be maintained as new genre names such as infotainment or reality soap suggest. Political discourse does not only appear in news or other information programs, but also in formats formerly reserved to other fields such as talk shows. Pinning down the language of news programs or the language of political media discourse becomes more and more impossible. The following part of this article therefore presents elements for an open and flexible framework for the analysis of (political) discourse in media.

Imagining the Audience

Who is the addressee and how is the relationship with the audience structured? These are central questions in the analysis of media texts. It is in fact the structuring of the producer–audience relationship and the ways in which audiences and their expectations concerning texts are imagined that determine how a text is shaped. Genres and text categories depend on this aspect. The notion of the target audience, which encompasses a spatial (local, regional, national, global) and/or a social (social status, income, age, gender) dimension is based on rigid and reified audience categories. Research on media coverage and definitions of target audiences are instruments of marketing research and correspond to criteria established by the advertising industry. Ang (1991) demonstrates that this approach is based on a discursive construct of audience that is unable to grasp the actual relationship between media and audiences and to conceive communication processes. She distinguishes between two main orientations: audience-as-public and audience-as-market. The first is generally associated with the public service media sector in which the addressee is seen as a citizen (of a state); the relationship with the audience is paternal and aims at transmitting values, habits, and tastes. It is linked to the so-called transmission model of communication, in which the transmission of a message and the ordered transfer of meaning is the intended consequence of the communication process.

The second configuration of audience is associated with the private commercial media sector. Audiences are addressed as consumers in a double sense: as consumers of the media product and as potential consumers of the products advertised in the programs. In the attention model of communication (McQuail, 1987), communication is considered successful as

soon as attention is actually raised in audiences. The transfer of meaning plays a secondary role. The scoop, the extraordinary, and the scandal gain in importance as means of awakening attention.

In the alternative media sector, the conception of the audience is determined by the idea of an active public that participates in social action and media production. The aim is to overcome the division between producers and audiences, to move closer to a situation in which the Other is able to represent itself, in which the heterogeneity of "authentic informants" is not reduced (Atton, 2002: 9). Alternative or third-sector media are consequently closer to the ideal of representing the multivoicedness of society in all three dimensions, which Bakhtin (Todorov, 1984: 56) has described: heterology (raznorečie), i.e., the diversity of discourses, heteroglossia (raznojazyčnie), i.e., the diversity of language(s), and heterophony (raznoglossie), i.e., the diversity of individual voices.

These different basic orientations in conceiving the producer–audience relationship result in preferences for particular media formats (e.g., authoritative information-centered programs, infotainment programs, and dialogic forms such as phone-in programs) and a choice of particular linguistic practices. They also determine the way in which discourses are being shaped, reproduced and transformed. It has, for example, been observed that the public service sector, at least in some segments of its program, is becoming more market-oriented and that formats and genres developed in a certain sector are taken up – sometimes in a transformed way – by others.

Modalities and Meanings

Media communication is inherently multimodal communication: this means that language in written and spoken form is one of several modes available for expressing a potential of meanings. For instance, in print media lay-out and image are available in addition to the written word; in radio, language is present in its spoken form, alongside music and different sounds; in television all the aforementioned modes can be drawn upon in a context in which the moving image holds a central position. Similarly, in computer-mediated communication, a wide range of modes is available. "A multimodal approach assumes that the message is 'spread across' all the modes of communication. If this is so, then each mode is a partial bearer of the overall meaning of the message. All modes, speech and writing included, are then seen as always partial bearers of meaning only. This is a fundamental challenge to hitherto current notions of 'language' as a full means of making meaning" (Kress, 2002: 6).

How these modes interact is not only a question of technical availability, but rather a question of social appropriation and convention, as Kress and van Leeuwen (2001) point out in their multimodal social semiotic theory. The interplay between the different modes has undergone substantial changes in media history. Writing was considered in many cultural environments as the central mode for the transfer of canonical knowledge and authoritative discourse. This practice of the predominance of the written text influenced radio production so that practically all radio texts in the early days of the medium were produced first in written form and then read in the radio broadcast. Even in television for some time, news broadcasts were read without a transmission of the image of the speaker, as it was considered that the moving image could distract attention. Linguistic practices and text genres from established media exerted and exert a considerable influence on new media and vice versa. Gradually with television, the image has moved into a central position. This has an impact also on political discourse, where appearances and the visible *mise-en-scene* of political events is becoming more important and must be considered as part of the political discourse. Live broadcasts of TV debates between representatives of different political orientations have for instance become central events in elections. Computer-mediated communication (e.g., Internet, e-mail) as well as other forms of new communication media (e.g., mobile phone news services) are increasingly present in the political field. The conversationalization of (political) discourse in the media (Fairclough, 1995: 9–10) has already gained in momentum with the image and television; possibly the new media will contribute to accelerating this development.

Text and Context

Media production is regulated by institutional routines, and media reception by everyday practices and arrangements, both depending on available resources. The production of media texts can be seen as a series of transformations, a chain of communicative events that link sources in the public domain to the private domain of media reception (Fairclough, 1995: 48–49).

Media production also encompasses the collection and selection of raw material. At each stage in media production, earlier versions of the text are transformed and recontextualized in ways that correspond to the priorities and goals of the current stage. In a multimodal context, different modes can become separated; for example, images can be subtitled with other texts or associated with other contexts.

During the production process, journalists can revert to different kinds of source material: political speeches, interviews, items already preprocessed by news agencies, press releases, archives, other media texts, etc. Current transformations in media production can be characterized on the one hand by an increasing specialization of journalists on narrower fields of reporting (specialization on topics, geographical areas, etc.) and on the other hand by a decreasing labor division between technical and journalistic parts of production. The journalist is not only responsible for the text, but also for the lay-out, the selection of images and even parts of the technical production. Replacing the typesetter, the reader and/or the sound technician, the journalist becomes the designer of a multimodal text. At the same time, because of the economic imperative of reducing the fixed costs in media enterprises, the amount of genuine journalistic investigation decreases in favor of ready-made products such as news agency material and preproduced elements and formats. Journalistic work is becoming more and more a matter of selection than of investigation and news production. This process is encouraged by an oligopolistic owner structure and practices of cross-referencing between different media. In relation to political discourse, this means that certain topics can make sometimes even unexpected media careers and become dominant in certain media areas (Siegert, 2003).

Another aspect frequently referred to in the context of media and political discourse is the acceleration of the rhythm of news production, especially with the rise of electronic media, which has in turn an accelerating influence the political agenda. That the political field responds to rhythms of urgencies was already raised by Platon, who drew attention to the differences between the actors in the *agora*, the public space, the political arena and philosophers who obey other rhythms. No doubt political and media agendas and discourses influence each other in multiple ways. Whereas earlier theories assumed a predominance of politics over the media or vice versa, contemporary approaches foreground interdependencies and interactions between the political and the media fields.

Media: Analysis and Methods

Introduction

The media provide a vast, continuous, and increasingly varied supply of linguistic data. The analytic methods which have been used to examine and explain these data are correspondingly diverse. From the early days of terrestrial television, with limited broadcasting hours, we have moved to 24-hour, multiple-channel satellite and digital broadcasting; radio stations on FM supply a wide choice of local and national programs; the Web has provided a whole new mode of electronic communication, including new ways of accessing print journalism, as most newspapers now publish on the Internet as well as in newsprint. 'Interactive' has become the digital buzzword for 21st-century media, as audiences of all kinds, readers, listeners, viewers, are invited to participate by phoning, e-mailing, texting (SMS messaging), joining bulletin boards and internet discussion groups. The 'voice' of the public is now as much a part of media discourse as the voice of the newscaster or commentator.

How has this proliferation of communicative data been approached by discourse analysts and linguists? What kind of media texts have been the focus of analysis and what kind of questions do we ask about such texts? This article presents some of the main analytic approaches to media discourse over the last two decades, and gives a summary of the concepts and issues that have been most salient in this work. The first section concentrates on aspects of participation: work dealing with analyses of speaker roles, voices, and identity in media discourse. The second section outlines aspects of content, dealing with work which has focused on how the media construct and represent the world. The final section addresses the particular characteristics of selected media genres, summarizing those aspects of media discourse which have been considered as context specific, institutionally oriented, and, as such, analyzably different from other forms of text and talk.

Analyzing Participation in Media Discourse

A major concept within interactional sociolinguistics, based around Goffman's notion of participation frameworks and 'footing' (Goffman, 1981), is the complex relationship between speakers, hearers, and the context of utterance. Goffman challenges the 'speaker/hearer' conduit models of communication and shows how these two categories can be described in far more contextually sensitive terms.

Participation Frameworks and Footings

Linguistic analyses of media discourse have drawn heavily on Goffman's work, particularly in relation to the discourse of public participation broadcasting (talk shows, radio phone-ins, panel debates, etc.), where members of the public interact with media professionals and other institutional representatives. These programs set up particular configurations of participant roles that are institutionally determined and generically specific. So, for example, in a British TV current affairs panel debate such as the BBC's

Introduction

The media provide a vast, continuous, and increasingly varied supply of linguistic data. The analytic methods which have been used to examine and explain these data are correspondingly diverse. From the early days of terrestrial television, with limited broadcasting hours, we have moved to 24-hour, multiple-channel satellite and digital broadcasting; radio stations on FM supply a wide choice of local and national programs; the Web has provided a whole new mode of electronic communication, including new ways of accessing print journalism, as most newspapers now publish on the Internet as well as in newsprint. 'Interactive' has become the digital buzzword for 21st-century media, as audiences of all kinds, readers, listeners, viewers, are invited to participate by phoning, e-mailing, texting (SMS messaging), joining bulletin boards and internet discussion groups. The 'voice' of the public is now as much a part of media discourse as the voice of the newscaster or commentator.

How has this proliferation of communicative data been approached by discourse analysts and linguists? What kind of media texts have been the focus of analysis and what kind of questions do we ask about such texts? This article presents some of the main analytic approaches to media discourse over the last two decades, and gives a summary of the concepts and issues that have been most salient in this work. The first section concentrates on aspects of participation: work dealing with analyses of speaker roles, voices, and identity in media discourse. The second section outlines aspects of content, dealing with work which has focused on how the media construct and represent the world. The final section addresses the particular characteristics of selected media genres, summarizing those aspects of media discourse which have been considered as context specific, institutionally oriented, and, as such, analyzably different from other forms of text and talk.

Analyzing Participation in Media Discourse

A major concept within interactional sociolinguistics, based around Goffman's notion of participation frameworks and 'footing' (Goffman, 1981), is the complex relationship between speakers, hearers, and the context of utterance. Goffman challenges the 'speaker/hearer' conduit models of communication and shows how these two categories can be described in far more contextually sensitive terms.

Participation Frameworks and Footings

Linguistic analyses of media discourse have drawn heavily on Goffman's work, particularly in relation to the discourse of public participation broadcasting (talk shows, radio phone-ins, panel debates, etc.), where members of the public interact with media professionals and other institutional representatives. These programs set up particular configurations of participant roles that are institutionally determined and generically specific. So, for example, in a British TV current affairs panel debate such as the BBC's

Question Time, the host, the members of the panel, and the audience occupy different participant roles as the program unfolds. All are 'ratified participants' in the communicative event, but the relationship between their position as speaker or hearer, addresser or addressee, is both complex and shifting. In his analysis of indirectly targeted utterances in this TV panel discussion, Levinson (1988: 221) pointed out that "having a set of participant role categories is one thing, but working out **who** stands in **which when** can be quite another, on a vastly greater plane of complexity."

A microanalytic account which addresses this complex relationship in mediated interaction is Hutchby's (1999) analysis of frame attunement and footing in talk radio phone-in call openings. Starting from Goffman's notion of 'mutually ratified participation' in situated interactions, Hutchby described how callers move from a state of 'incipient' speakership to actual speakership and topic initiation in the first three seconds of these, usually routine, opening sequences, such as the following:

> Host: Joan calling from Clapham now. Good morning.
> Caller: Good morning Brian. Erm:, I (li) I also agree that the . . . (Hutchby, 1999: 46)

He argues that the sequential organization of the call opening (i.e., host goes first, caller goes second, with a specialized distribution of turn types; see 'Media Talk as "Specialized" Speech Exchange Systems' below) is only partly how institutionality is achieved in this context. Temporality is also crucial here; Hutchby identifies the moment-by-moment shifts of footing hosts and callers move through (i.e., the greeting, 'buffer' [erm], and topic initiation) in order to effect a transition from the private sphere of the caller into the public sphere of the broadcast.

In addition to providing a set of categories and a description of the range of participant roles in a TV or radio broadcast, the analysis of participant roles and turn-taking positions in these programs enables us to examine the relationship between the institutional and the communicative context for talk. An analysis of the participation framework also enables us to examine typically who does what in those roles, i.e., the type of turns taken by each participant. As an illustration, a popular radio phone-in format will typically involve a host, a studio guest, and a caller (as well as the wider listening audience). In their institutional roles, these participants do different things: the role of the host is to mediate interaction between caller and guest, while the caller asks the questions and the guest gives the answers. However, although the caller occupies the potentially powerful role of questioner, their right of reply is not given in this context; the third-turn receipt of the answer is generally taken by the host, who may or may not offer a further turn to the caller. This third turn is a host's resource for controlling the trajectory of the talk (Thornborrow, 2002).

Participation and Identity in Public Participation Broadcasting

Often linked to the analysis of speaker roles, another analytic concept used to examine participation in media discourse is the use of the categories 'expert' and 'lay.' These terms describe the institutional and social status of participants, and have a bearing on the kind of talk that they will be invited to produce. In a discussion of the participation framework in *Kilroy*, a former British TV talk show, Livingstone and Lunt described the difference between expert and lay discourse. Talk by lay audience members is real, authentic, grounded in experience, 'hot'; while expert talk is 'cold': artificial, fragmented, and ungrounded (Livingstone and Lunt, 1994: 102). Experts speak for others, while the audience speak for themselves. Again, using Goffman's model of 'footing' to describe the relationship of a speaker to their utterance, it was claimed that a lay participant speaks from a position of 'animator, author and principal,' in their own voice, in their own words, with commitment to what they say, while experts talk as animator rather than author or principal, speaking with an institutional voice, for 'the profession' and not from personal experience or commitment.

The theme of authenticity, and what is meant by an authentic voice in media discourse, has been taken up in Thornborrow and van Leeuwen (2001). Another way of thinking about the expert/lay dichotomy in public participation broadcasting is to look at how speakers identify themselves in this context. While some participants in these programs are identified by name and by their institutional relevance to the topic at hand by the host, so-called lay participants have to do this work for themselves. Callers to radio phone-ins, and participants in talk show debates, routinely construct a relevant situated identity in relation to what they have to say:

> Caller: hello yes uh my question uh to the prime minister is on health .hh I'm a nurse in (.) a London teaching hospital and (.) my question is this [–] (Thornborrow, 2001b: 464)

This process of 'discursive grounding' provides a relevant frame for their contribution to the talk. A similar kind of action can be found in the way callers legitimize their opinions and viewpoints through a process Hutchby (2001: 495) called 'witnessing': "they bring into play claims that are – or are

assumed to be – incontrovertible, such as being a member of the category of pensioners, or having seen an event with one's own eyes."

Participation and Identity on the Net

The question of participant identity is also one that has been explored in relation to computer-mediated communication (CMC), where participation frameworks are configured differently again from broadcast radio or television media genres. It has been suggested that one of the primary features of Web-based communication is the option not to reveal aspects of one's social identity. It is possible to conceal age, gender, ethnic background, and class – the traditional sociolinguistic 'big four' variables – and construct a persona which is free from visual or spoken identity markers. The advantages of Web-based communication have been studied from the perspective of people who suffer from some kind of impediment or disability in face-to-face, or voice-to-voice, communicative situations, and for whom interaction is facilitated through the written modes of e-mail and messaging (cf. Lupton, 2002).

However, the construction of a virtual identity can clearly have negative effects when used to intentionally deceive others. In spite of the initial view that the Internet was going to release users from conventional social hierarchies and prejudices, research has shown that in CMC, people still make assumptions about who they are communicating with based on stereotypical interpretations of gendered behavior (cf. Deuel, 1996).

Analyzing Representation and Ideology in Media Discourse

Turning from participation in mediated interaction to the subject matter of media discourse, the analysis of content – particularly of print and broadcast news – was the focus of research in media studies begun in the mid-1970s by a group known as the Glasgow Media Group (1976, 1980). This concern with content as ideological representation was also taken up from a linguistic perspective in the development of a body of work known as 'critical linguistics' (cf. Kress and Hodge, 1976).

Critical Linguistics and Critical Discourse Analysis

In terms of media analysis, critical linguists began to look in detail at the linguistic structures in news reporting, particularly at the processes of grammatical and lexical selection and representation. Basing their claim on what has been described as a 'weak version' of the Sapir–Whorf hypothesis, they argued that ideological positions can to some degree be 'read off' from linguistic form. Linguistic processes such as transitivity, nominalization, and passivization realized as systematic textual choices present different ideological versions, or theories, of the world, and of events, actors, and actions in it (Fowler, 1991; Simpson, 1993).

Driven to some extent by the political context at that time (in Britain this was characterized by monetarist economics, industrial unrest, and, as in the United States, hard-line nuclear defense policies), this work was developed in order to challenge and critique the dominant ideologies of Thatcherism and Reaganism in a range of textual genres, from media news reports to political speeches and policy documents (Chilton, 1988; Fairclough, 1995). Montgomery's (1996) analysis of the news reports of the British coal miners' strike in 1983 showed how contrasting representations of what is ostensibly the same event can be produced through different selections of linguistic forms. Key theories which have been elaborated by Norman Fairclough within the field of critical discourse analysis (CDA) are 'synthetic personalization' and the 'marketization' of discourse, the 'commodification' of social institutional processes such as education, and the 'mediatization' of politics and government. With the change in the political agenda brought about by the election of a Labour government in Britain in 1997, Fairclough (2000) turned the spotlight on the language of Tony Blair's New Labour, analyzing the rhetorical construction of political spin: the control over the way politicians use language to communicate their ideas through the media.

The agenda of CDA, as it has been set out by Norman Fairclough (1995), Teun van Dijk (1988), and their colleagues across Europe over the last 10 to 15 years (Wodak and Meyer, 2002), is to provide a set of critical tools and analytic methods with which to challenge and critique ideological discourse practices. Examples of this approach as it is applied to media texts can be found in van Dijk's analysis of racist discourse in the press (1991) and in Ruth Wodak's research into attitudes towards immigration, racism, and the European Union. Gunter Kress and Theo van Leeuwen (1998) also take a critical approach to media texts in their work on the semiotics of newspaper layouts. This is an analytic approach which takes into account the organization of not just the verbal, but also the visual aspects of mediated communication, and offers a multimodal analysis of the components implicated in the production of textual meanings.

The theoretical grounding of CDA and its methods are not without critics. There can be a tendency to

overtheorize at the expense of paying close attention to empirical data, and a proliferation of technical terms that are not always clearly defined. As a methodological 'toolkit' for the analysis of media (or indeed other) texts, however, one of the clearest and most systematic accounts of the application of CDA to media texts can be found in van Dijk (1998). Here he laid out a set of analytic parameters (social functions, cognitive structures, and discursive expression and reproduction) and summarized the relationship between them, demonstrating how they can be used to unpack the ideologies which organize social attitudes and opinions in news stories.

Despite these criticisms, it is clear that what versions of discourse analysis taking a sociocritical approach to textual data can convincingly do is show the kind of underlying background assumptions and prevailing discourses which structure hegemonic social meanings in texts. As an example, Justine Coupland's work on the representation of social groups in a range of advertising texts from dating ads to face cream ads focuses on the social construction of age and identity. Coupland uses the concept of commodification of the self to analyze the discourse of dating adverts (1996) and more recently, to analyze the ideological discourse practices involved in advertising skin care products (2003), i.e., the presupposition in that ageing is problematic.

CDA has established itself as one of the principal methods for analyzing and critically evaluating the content of media discourse broadly understood, whether in spoken mode (see Fairclough, 1995, for analyses of popular television series in Britain such as *Crimewatch UK* or *Medicine Now*) or in the print media, from advertising to newspaper reporting.

Analyzing Generic Properties of Media Texts

The analysis of representational aspects of media discourse as outlined above is only part of the story. The analysis of media discourse as a particular form of **talk** has been the subject of a wide spectrum of research, which has focused on unscripted, broadcast talk. This is first and foremost 'public' talk (Scannell, 1991), since one of the most significant ways in which media talk differs from talk in many other nonmediated contexts is the fact that it is produced for an audience that is not copresent (often termed 'the overhearing audience'). Most of the major analytic work which focuses on mediated talk as interaction has been undertaken in the field of conversation analysis (CA).

Media Talk as 'Specialized' Speech Exchange Systems

From the perspective of CA, the media have provided a highly fruitful source of institutional data. Examining mediated interaction as a context for talk which has a restricted and preallocated turn-taking system, and a specialized distribution of turn types, conversation analysts have been able to describe the organization of talk in media genres such as news interviews and public participation programs on both radio and television. The turn-taking system of a news interview is "a course of interaction" (Clayman and Heritage, 2002: 13) designed to maintain the audience as addressee. Specifically, news interview openings set agendas and regulate interviewees' access to interaction, while closings are managed to limit abruptness within strict time limits. The turn-taking process involves one party asking questions (the interviewer) and the other responding to them (the interviewee); furthermore, it always falls to the interviewer to respond to an answer in third-turn receipt position, which enables them to do things such as reformulate an answer either positively, negatively, or aggressively.

This speech exchange system is very different from conversational turn taking, where there is no preallocation of speakers or specialized distribution of turns.

Issues of agenda setting, agenda shifting, and neutrality in news interviews have also been addressed by conversation analysts: for example, the design of interviewer questions, and the various strategies deployed by interviewees in answering (or not answering) the question. Clayman and Heritage pointed out that interviewers "often work to place some degree of distance between themselves and their more overtly opinionated remarks" (2002: 152) and the most usual way of doing this is by attributing that point of view to a third party, as in the following example:

> IR: .hhh People have used the phrase 'concentration camps': and the Bosnians themselves have used that phrase. Do you believe there's any justification for that at all? (Clayman and Heritage, 2002: 153)

Neutrality is jointly produced by both interviewer and interviewee, and interviewees collaborate in maintaining the neutralistic stance by not challenging third-party assertions, although as Clayman and Heritage pointed out, they generally tend to refute them. Current styles of adversarial interviewing, and the increase of debate interviews where multiple interviewees take part in the interaction, usually with the intention of providing institutional

'balance,' are now also beginning to be investigated by conversation analysts as the genre changes and evolves.

It is not only the turn sequences of questions and answers in news interviews that have been shown to be contextually specific. This is also the case in other broadcasts such radio phone-in programs, where callers can engage in various kinds of questioning activity. An example of how mediated interaction can be seen to differ from conversational interaction can be found in Hutchby's (1995) analysis of the design of advice-giving turns in a radio phone-in program. In this context again, listeners have to be maintained as ratified participants in the talk event, as well as the host, expert adviser, and callers. The advice giver manages this by moving from the particular to the general, addressing not only the current caller with the problem, but all listeners who may also have the same problem, thus making their advice relevant for not just one addressee but for their wider audience.

The design of talk for this 'overhearing audience' has been one of the central concepts in conversation-analytic approaches to media discourse, and it has also been taken up more generally by discourse analysts interested in the particular, public, nature of broadcast talk.

Media Talk as 'Performance'

Drawing on the notion that mediated communication is public talk produced for the listening and viewing audience, a body of work has emerged which analyzes media discourse as 'performance.' With specific reference to television talk shows, Tolson (2001b) examined the ways in which interaction in these programs is 'doubly articulated,' i.e., designed for its immediate recipients as well as the studio and/or viewing audience. Focusing on discourse genres such as conflict talk, argument, narrative, and therapy talk, which characterize many TV talk shows, these studies show how unscripted talk produced in such contexts is nevertheless performed for its audience. And such talk can be considered as "a form of play with pragmatic expectations of conversational practice" (Tolson, 2001a). For instance, Myers (2001) examined how a topic is made into an issue on the *Jerry Springer* show through four distinct stages: defining and representing stances, making those stances controversial, making them dramatic, then finally, making them meaningful. Wood (2001) looked at how Kilroy (former host of a British talk show of the same name) pursues an agenda through particular types of question and answer sequences which maximize conflict and enhance levels of 'televisuality.' She argued that in these shows it is not simply a case of lay speakers being given a voice in the sense that ordinary people are invited to talk about their everyday lifeworlds; rather that the talk is constructed and managed in order to produce debate and dissent – i.e., the pursuit and performance of conflict. Similarly, Thornborrow (2001b) showed how narrative discourse of lay participants is elicited and managed in order to maximize the most dramatic moments of a story for the audience, examining the role of the host as narrative dramatizer as well as narrative elicitor.

Media Discourse Genres: Some Examples

The fact that mediated communication gives rise to highly context specific genres of discourse has also been addressed by sociolinguists interested in describing forms of talk generated by broadcasting institutions, from DJ talk to sports commentary. Many of these media discourse genres have highly distinctive linguistic and pragmatic features, not only in terms of their content, but also in terms of their register, modes of address, and deictic format.

DJ Radio Talk In a seminal paper on DJ talk, following Goffman (1981), Montgomery (1986) produced a further challenge to the model of mass communication which understands the communicative event in terms of a single speaker addressing a mass audience. Basing his analysis on pragmatic concepts of deixis and speech act theory, Montgomery showed how monologic DJ talk foregrounds an interpersonal relationship between the DJ and his audience, continually shifting its mode of address between different constituencies in the listening audience. Interpersonal features of DJ talk include simulating copresence through the linguistic devices of social and spatial deixis, the use of speech acts that require responses, e.g., questions and directives, and the use of expressives, e.g., congratulation and commiseration.

Montgomery also drew on Goffman's concept of participation frameworks and footing in order to examine alignments between speaker (DJ) and an array of hearers, through a process of interpolation, e.g.:

> Okay Fleet Street
> (they're all awake now)
> I have news of a rock star (Montgomery, 1986: 437)

In this way, Radio DJs constantly realign their talk to address different segments of the audience, from the individual to the collective, but very rarely to the general mass.

Mediated Narratives Narrative discourse is pervasive in broadcasting. In addition to the fictional genres of film, drama, soap, and sitcom, contexts for

storytelling include news, documentary, TV talk shows and talk radio, broadcasting, and, most recently, reality TV. An early account of how private stories are produced as public discourse is Montgomery's study of narrative discourse on a popular British radio station. In his analysis of 'Our Tune,' a regular slot through the 1970s and 80s which featured listeners' stories of overcoming personal difficulties in their lives, Montgomery used a Labovian framework of oral narrative analysis to show how different components of the stories become adapted to this particular mediated event. The DJ becomes the 'epistolary narrator' transforming the story from its original form of a private letter to the public medium of the spoken word. Through the use of 'empathetic orientation' towards the story protagonists, and specialized evaluation clauses that Montgomery calls 'generic maxims,' the DJ reconfigures the relationship between the teller, the story, and its recipients for its new, broadcast context (Montgomery, 1991).

More recently, the design features and discourse structure of storytelling by lay participants on British and American talk shows have been examined from a range of analytical perspectives (cf. Thornborrow, 1997, 2001b; Lorenzo-Dus, 2003). Drawing on CA, as well as the pragmatics of facework, Goffman's concept of role relations, and Gidden's notion of the 'project of the self,' this work examines aspects of situated narrative form as well as its contextual function as a component of public participation broadcasting. Telling stories becomes a quasitherapeutic act, what Lorenzo Dus called 'emotional DIY,' conducted in the public domain.

Live Commentary Relaying live events to a listening or TV viewing audience has become one of the primary functions of public broadcasting. The language of radio and television commentary, from sporting events to state ceremonies, is distinctive in its form, and linguistically particularly interesting as a media discourse genre. As Stephanie Marriott (1997: 194–195) explained, the commentator is "perpetually poised on the edge of the new," and commentary constructs a shared "emergent present" between speakers and recipients. For radio, this involves a shared temporal framework, and in the case of television, also a shared spatial perspective: the visual field of the television monitor in the studio and the television screen of the viewer. This intersubjectivity between commentator and viewer is created linguistically through a high instance of deictic expressions which enforce the mutual, shared experience of the here and now, of first- and second-person pronouns which foreground the interpersonal relationship between speaker and hearer, of hedged opinions which allow for the uncertainty of the moment, and of present and present perfect tenses which locate events in the 'now' and the 'just now.' Here are some examples from a bowls match commentary, and a snooker game:

1. Well, Mervyn, if he can make contact with his own nearest blue bowl and punch out the nearest McMahon bowl, could establish a set and match winning lie – he's running after it – he rather likes it – he's thereabouts – he's got it.
2. I promise you the pressure has got to be the greatest ever.
3. Well that's worked out exceptionally well for Steve. (Marriott, 1997: 194)

'Netspeak,' E-mails, and SMS Messaging To conclude this selection of linguistic analyses of media genres, no account would be complete without a brief comment on the most recent phenomena of the electronic age of communication, the Internet and the cell phone. These media not only give rise to different participation frameworks for communication (see above) but also, it is claimed, to new forms of written language. David Crystal (2001) examined some of the changes that the new medium of the Internet has brought about, e.g., neologisms, new conventions in formatting and punctuation, and the use of graphic symbols (emoticons) as expressive and evaluative discourse markers. Crystal takes the view that language is not only changing on the Internet, but it is changing **because of** the Internet. Others are more cautious in their claims, asking whether language use on the Internet is really so different from other varieties and registers to merit a label of its own. However, a consensus seems to be developing that 'netspeak' or 'netlingo' is at the very least a form of written communication that shares some characteristics with spoken language, and these characteristics can be contextually identified and linguistically described.

E-mail communication has been described both as "letters by phone" and as "speech by other means" (Baron, 2003), capturing the difficulty of pinning down precisely what is distinctive about this form of communication. The language style is informal (but not as informal as face-to-face speech), a fast response is expected (but doesn't always get acknowledged), an e-mail is generally intended for a limited audience (but leaves a trace and can be forwarded to others without the sender's knowledge), and it is often treated as ephemeral: unedited and with the production errors left in (but it can be printed out, edited, and traced). The synchronous (real time) interaction that takes place in online chatrooms, with instant messaging, or in multiple user dialogs can be as complex as

multiparty talk: it is characterized by a high level of 'addressivity,' short turns, different conversational strands running simultaneously, and back channel support/minimal response tokens (Thurlow *et al.*, 2003) While this form of communication is immediate, sharing many features of face-to-face interaction, it nevertheless relies on the use of the keyboard. The need for interactional speed leads to the development of specialized forms such as letter homophones, acronyms, and hybrids of both, capitalization for stress and emphasis, stylized spelling, and the use of emoticons and other graphic symbols which form a code, a linguistic variety used in this specialized context, which, like all mediated interaction, is constantly evolving.

Media: Pragmatics

Today, many, if not most, people in the world live in societies that can be described as 'mediatized societies.' A mediatized society is one in which the meaning processes, or discourses, provided by the communication media play an increasing, even overwhelming, role in the way society is economically, politically, and culturally organized, affecting the way we as individuals and groups think about everything and thus what we do in all contexts of life.

The mediatized society affects us in whatever social roles we have to fill in everyday life. As citizens, we are concerned about the organization and power relations of society; as consumers, we have to take care of our material, intellectual, and wider cultural needs; and as human beings, we have to organize our private lives as individuals, couples, or families on a daily, weekly, and yearly basis.

In all these respects, we are surrounded and affected by the sea of discursive meanings produced by the media. It is therefore mandatory for the understanding of modern society to understand the complex social meaning processes that have media at their core. This requires a 'pragmatics of media' that explores media discourses in their situational and social contexts.

Approaches to the Study of Media Discourses

It has gradually become accepted, at least in principle, that in order to understand the workings of the mediatized society it is necessary to adopt a holistic perspective of the media, according to which it is necessary to not just analyze the media texts but also to consider the production and reception processes involved in media texts, as well as the macro-social context, as interdependent objects of empirical analysis. For a number of years, these processes were conceptualized theoretically in semiotic terms as a signifying process, along the lines laid down by the so-called 'encoding/decoding' model of mass communication (Hall, 1980) (**Figure 1**).

This model implies that any study of a media genre or of the media coverage of real-world events must research, in addition to the textual aspects, the production and reception stages around the text. The

Today, many, if not most, people in the world live in societies that can be described as 'mediatized societies.' A mediatized society is one in which the meaning processes, or discourses, provided by the communication media play an increasing, even overwhelming, role in the way society is economically, politically, and culturally organized, affecting the way we as individuals and groups think about everything and thus what we do in all contexts of life.

The mediatized society affects us in whatever social roles we have to fill in everyday life. As citizens, we are concerned about the organization and power relations of society; as consumers, we have to take care of our material, intellectual, and wider cultural needs; and as human beings, we have to organize our private lives as individuals, couples, or families on a daily, weekly, and yearly basis.

In all these respects, we are surrounded and affected by the sea of discursive meanings produced by the media. It is therefore mandatory for the understanding of modern society to understand the complex social meaning processes that have media at their core. This requires a 'pragmatics of media' that explores media discourses in their situational and social contexts.

Approaches to the Study of Media Discourses

It has gradually become accepted, at least in principle, that in order to understand the workings of the mediatized society it is necessary to adopt a holistic perspective of the media, according to which it is necessary to not just analyze the media texts but also to consider the production and reception processes involved in media texts, as well as the macro-social context, as interdependent objects of empirical analysis. For a number of years, these processes were conceptualized theoretically in semiotic terms as a signifying process, along the lines laid down by the so-called 'encoding/decoding' model of mass communication (Hall, 1980) (Figure 1).

This model implies that any study of a media genre or of the media coverage of real-world events must research, in addition to the textual aspects, the production and reception stages around the text. The

Figure 1 The encoding/decoding model. Reproduced from Hall S (1980). 'Encoding/decoding' In Hall S, Hobson D, Lowe A & Willis P (eds.) *Culture, media, language*. London: Hutchinson.

model serves to remind analysts that in analyzing a text, they are dealing not with a fixed structure of meaning, but with a volatile phenomenon resulting from the signifying codes of both the producers and the recipients of the text. Crucially, these codes need not be identical; indeed, since the codes at the disposal of any individual consist of a unique assemblage of the meanings assimilated during that person's life history, the codes of producers and receivers are in principle nonidentical. Consequently, one should expect to find multiple meanings resulting from different individuals' reading of a news bulletin, an advertisement, or a TV reality show.

On the other hand, people also belong to interpretive communities (constituted by such factors as class, ethnicity, gender, age, profession, location, etc.) in which meanings are shared to a large extent (Schrøder, 1994). Therefore, a purely textual analysis of a media text can still be justified, as long as the analytical findings are offered cautiously as potential meanings, or made on behalf of a specific interpretive community whose sign universe makes these meanings plausible.

In recent years, the term 'discourse analysis' has gained general acceptance as the way to characterize the theoretical and methodological framework, often holistic, within which analyses of media language and communication are carried out in the interdisciplinary field of media studies, cultural studies, and communication studies. For a general introduction to the most prominent distinctive approaches to discourse analysis in the social sciences and the humanities, see Jørgensen and Phillips (2002).

First-Generation Discourse Analysis: 'Critical Linguistics'

Critical linguistics developed in the 1970s as an influential school of early discourse analysis because it was able to demonstrate the close relationship between the detailed linguistic choices and the production of ideology in media texts (especially news) and, by implication, to explain how media ideology contributed to the reproduction of a social order characterized by inequality and oppression (Fowler *et al.*, 1979).

Critical linguistics adheres to an early version of linguistic constructionism, according to which the words of our language function as a conventionalized mental grid through which we perceive reality. Words constitute the reality that they designate, and when newspapers inform about social states and events they inevitably construct those very states and events.

Going one step further, critical linguistics claims that also the syntactic choices made in a text have a constraining effect on the construction of social reality. The most important of such syntactic–ideological processes are those of passivization and nominalization.

This should not be taken to mean that the verbal choices in news reports can be made by journalists at will. As mentioned previously, the formation of public opinion through the media in capitalist societies is controlled by those with economic and social power over the mass media, who will see to it that social affairs are represented in such a manner as to not jeopardize their interests and privileges. Consequently, there is a power dimension in all public communication, an ideological thrust that by its sheer omnipresence in the aggregate media landscape manages to establish the current social arrangements as natural and inevitable and to discredit alternative perspectives as being contrary to common sense.

It is the task of critical linguists to expose the ideology conveyed by the media, to demonstrate that news reports of social affairs are indeed constructed and that they systematically portray a state of affairs that is not in the best interest of the majority of the population.

It is thus the goal of detailed linguistic analysis to demonstrate how various seemingly innocent linguistic features in a text convey ideological meanings that reproduce existing unequal power relations. Through linguistic analysis of the news text, the critical linguist is able to expose "warped versions of reality" (Fowler, 1985: 68).

Drawing on Halliday's (1978) theory of functional grammar and social semiotic, innumerable publications by the core group of critical linguists through the late 1970s and the 1980s have described the specific linguistic features that "will probably repay close examination" (Fowler, 1985: 68; see Fowler *et al.*, 1979; Hodge and Kress, 1988). The 'checklist' presented in Fowler (1985) includes the following:

1. Lexical processes: Under this heading, critical linguists examine the way a text uses different lexical fields through the choice of vocabulary (including metaphors) from specific areas of experience, such as scientific vocabulary in a cosmetics ad or management jargon in a political text.
2. Transitivity designates the textual construction of reality through the description of participants and processes, as reflected in the nouns and verbs of the text. As Fowler (1985: 70) states, "Different choices of transitivity structure will add up to different worldviews."
3. Syntactic transformations: Critical linguists believe that certain syntactic transformations of sentences, particularly those labeled 'passivization' and 'nominalization,' are ideologically problematic

because they may make agency invisible and thereby obscure who did what to whom or significantly change the relative prominence of the participants.

4. Modality: Under this heading, analysts search for the different linguistic features (e.g., modal verbs and adverbs) through which speakers and writers may express their attitudes toward the events depicted by the sentences in which they occur.
5. Speech acts and turn-taking: Analysts should consider for each sentence or utterance what speech act it appears to perform and how it may build positions of power in the situation in which it is written or spoken. The analyst may also produce interesting insights about the power aspect of interpersonal interaction by examining the turn-taking patterns of different kinds of dialogic and discussion-oriented TV programs: who can speak when and about what, who can open up new topics, etc.
6. Implicature: This linguistic feature is best explained as the meaning that can be found by 'reading between the lines.' There is more to meaning than what is said, and an essential part of the meaning communicated through language is inferred by the speakers from the situational and social context.
7. Address and personal reference: Under this heading, the analyst may consider how different stylistic choices can be seen as addressing some readers rather than others (such as a Latinate vocabulary addressing the educated), how naming conventions affect the degree of formality, and how personal pronouns (*you* used with simultaneous individual and mass appeal in ads, and *we* used to include or exclude listeners from the group the speaker belongs to) may affect interpersonal relationships.

This checklist of potentially ideology-bearing features developed by 'critical linguistics' has found its way into many later forms of qualitative textual analysis of the media, including the approaches to discourse analysis discussed later.

It is not evident, however, that they are all equally useful for the production of insights about the media's signifying processes. For instance, transitivity analysis requires an immensely time-consuming scrutiny of textual details, and even when a kind of ideological pattern does emerge from the analysis (see the case analyzed in Fowler, 1985), it is usually a fairly predictable one that even a cursory glance at the text would have discovered. Therefore, especially for students with little linguistic training, transitivity analysis is usually not worth the effort.

Regarding the 'syntactic transformations' of nominalization and passivization, it is doubtful whether the claims of their mystifying effects are really warranted. In most cases, they appear to be based on erroneous assumptions about the 'nonrecoverability' of the transformed or deleted linguistic items (Trew, 1979). It seems to be equally probable that on the basis of their overall knowledge of the world, their familiarity with the media agenda and yesterday's news reports, and their general communicative competence, average newsreaders will have no difficulty in reconstructing who did what to whom, despite the agent having been deleted from the sentence through a passive construction. Interestingly, an empirical study of readers' reception of newspaper articles previously analyzed by Trew found that the syntactically constructed ideology of the articles did not determine the readers' views of the events reported. Their views depended on their identities and life histories as much as on an ideological effect attributable to the news language (Sigman and Fry, 1985).

Critical Discourse Analysis of the Media

Although clearly intellectually rooted in critical linguistics, critical discourse analysis (CDA), as developed by Norman Fairclough and others since the late 1980s, represents a significant theoretical and methodological advance toward the interdisciplinary study of media discourse (Fairclough, 1995, 2003; van Dijk, 2001; Wodak and Reisigl, 2001). Rather than concerning itself just with the media's textual reproduction of ideology, CDA sets up a comprehensive theoretical framework that relates textual features systematically to the situations in which those texts are produced and consumed and to the larger social processes of the society in question.

This theoretical framework is often described through a model of three embedded boxes (Figure 2),

Figure 2 Dimensions of analysis in CDA. Reproduced with permission from Fairclough (1995).

each of which represents a dimension of analysis (Fairclough, 1995: 59).

'Texts' stand at the core of the model and are explored through the same forms of linguistic analysis that are used by critical linguistics, with the purpose of illuminating the way the text represents social reality and the way it portrays the identities and relations of the participants in the textual universe.

The second dimension of analysis deals with 'discourse practices' – that is, the processes through which the media text is produced in media institutions and consumed, or 'decoded,' by the audiences and users in the context of everyday life. The discourse practices are seen as mediators between texts and macrolevel 'sociocultural practices,' which constitute the third dimension of analysis. On this level, the phenomena brought to light by the other two dimensions are viewed in relation to the macrosocial processes that characterize the societal 'order of discourse' at a given point in time (*see* **Discourse, Foucauldian Approach**).

CDA, in contrast to critical linguistics, is founded on an acute awareness of the ambivalent role of media discourses in the social formation. Inscribing his model into the current debates about 'structure' versus 'agency' (Beck *et al.*, 1994; Giddens, 1984), Fairclough placed his approach within a social constructionist theory of society according to which media discourses are constituted by social practices and also are constitutive of such practices.

This means that, on the one hand, mainstream media discourses are constrained, by the economic and political frameworks within which they operate, to produce versions of reality that are on the whole supportive of the existing social order. On the other hand, the fact that the existing social order is not monolithic but characterized by diversity and ideological struggle means that the faithful representation of this very reality must also be characterized by diversity and struggle, and the outcome of such representational struggles is by no means certain to always favor the power elites. The end result of the media's discursive practices in a given area is therefore often uneasily balanced between social reproduction and social change, between convention and innovation.

For example, the macrosocial phenomenon that Fairclough terms the 'conversationalization' of public discourse in the media (i.e., the increasing occurrence of informal speech forms and colloquial expressions in television news and documentary programs) can be seen as sometimes working to support ideologically hegemonic forces because it may trivialize and simplify complex social relationships. However, conversationalization may also serve as a generator of cultural democratization because it may make complex issues easier to understand: "The communicative style of broadcasting lies at the intersection of ... democratizing, legitimizing, and marketing pressures, and its ambivalence follows from that" (Fairclough, 1995: 149).

'Intertextuality' is a key analytical concept in CDA designating a principle of textual construction and recognition encompassing several distinct processes. It is meant to cover the basic fact that any text is indebted to innumerable previous source texts and will itself potentially become a source for an infinite number of future texts. Intertextuality also includes the way a text may stylistically echo one or more well-established genres, or particular well-known texts (e.g., when a TV commercial echoes the Western genre or a specific Western film), as well as the way a text may use specific recognizable passages from other texts (e.g., when a U.S. presidential hopeful inserts into his speech a passage from the Declaration of Independence or the Bible, or when news stories rely on direct or indirect quotations of a politician's statements).

Finally, the intertextual perspective means that the analyst should search for the way the particular text may draw on different 'orders of discourse.' This is a term that Fairclough borrowed from Foucault and that he defined as "a structured configuration of genres and discourses ... associated with a given social domain" (Fairclough, 1998: 145) with clear implications for the regime of knowledge and power that rules within the particular domain. In the case of political discourse in the media, one may find that the conventional political order of discourse is intermingled with scientific and technological orders of discourse, the order of discourse of grassroots politics, the everyday order of discourse, etc. to create a new hybrid superordinate order of discourse that may herald innovative processes in the political domain.

The main limitation of CDA, which in no way invalidates its achievement as a stimulating theoretical framework for media analysis, is the lack of empirical consideration of the middle level of analysis, the discourse practices. Fairclough deliberately excludes this aspect from his own analyses, stating that "my emphasis will be upon linguistic analysis of texts...I am not concerned ... with direct analysis of production or consumption of texts" (Fairclough, 1995: 62). It is nevertheless a limitation that becomes acute if the analyst wants to discuss the sociocultural implications for audiences of the meanings found through textual analysis. Very few researchers have undertaken a fully holistic, empirical study of media discourses examining the text-mediated communicative circuit between senders and recipients. Among the exceptions are Swales and Rogers's (1995) study

of corporate mission statements and the studies of the news circuit by Gavin (1998) and Deacon *et al.* (1999).

Conversation Analysis and Discursive Psychology

A third important discourse analytical approach has been developed mainly by scholars in the field of discursive psychology (Potter and Wetherell, 1987). Among its heterogeneous ancestry, there is no doubt that the ethnomethodology/conversation analysis complex has had the most formative influence on the approach with regard to the actual procedures of analysis. It is the analytical aim of conversation analysis to explore the situational micromechanics of verbal interaction, illuminating among other things the speakers' management of turn-taking processes through adjacency pairs, the role played by silences and interruptions in the flow of interaction, the way speakers manage topic development and topic change, mechanisms for 'opening up closings,' and so on (for general introductions to conversation analysis, see Nofsinger (1991) or Have (1999)).

Like conversation analysis, discursive psychology takes its point of departure in the situational context in which language is used. However, it does so in order to explore how the micromechanics of verbal interaction affect wider cultural, political, and social processes, for instance, in the analysis of nationalism in institutional and everyday settings (Billig, 1995, chap. 5), and in order to reconceptualize the study within psychology and social psychology of topics such as attitudes, memory, and attribution (Potter and Wetherell, 1987).

The study of the mass media is not central to discourse psychology proper. However, it is clear that the approach has a lot to offer theoretically and analytically in this respect as the electronic media become increasingly dominated by programs that borrow from or replicate the verbal interaction of everyday life and as the digital interactive media open up enticing prospects of virtual communities based on verbal exchange (Hutchby, 2001) (*see* **Cognitive Technology**).

Briefly characterized, discourse psychology analyzes talk in everyday situations because it is in interpersonal encounters that an important part of social reality is constructed, as speakers position themselves and each other in situational roles according to their individual and social interests. Discourse psychology is particularly concerned with the way speakers engage in fact construction – that is, the way they attempt to establish their accounts, or 'versions,' of social events as true and factual and to undermine the factuality and truth of the versions of their interlocutors – a focus that is particularly appropriate to investigate many television news interviews and studio debate programs (Potter, 1996).

When they produce their accounts of social events, staking a claim for their version, participants are drawing on meaning resources based on interpretive repertoires, a kind of 'framework of understanding' (Potter and Wetherell, 1996: 89):

> By interpretative repertoires we mean broadly discernible clusters of terms, descriptions, and figures of speech often assembled around metaphors or vivid images. In more structuralist language we can talk of these things as systems of signification and as the building blocks used for manufacturing versions of actions, self, and social structures in talk.

In a study of the discursive construction of politics in Danish media, Phillips and Schrøder (2004) found that the media made sense of the political through six different interpretative repertoires for understanding politics in a wide sense, ranging from the parliamentary arena, through the subpolitical arena of grassroots activism, to the life–political arena of political consumption in daily life: 1. 'parliament-at-work,' offering a positive perspective on capable and active politicians; 2. 'the dirty underside of the party game,' in which politicians are seen as scheming and manipulative; 3. 'populism,' pitching sensible citizens against distant, ignorant, and arrogant politicians representing 'the system'; 4. 'grassroots activism,' in which citizens can make a difference by joining forces around single issues; 5. 'everyday politics,' where the negotiation of individual responsibility for social issues results in small-scale political action; and 6. 'politics as a meta-phenomenon,' an interpretive repertoire that constructs an outside evaluative and reflective perspective on the mechanics and limits of political institutions and agents.

The important point about such repertoires is that they are not mutually exclusive but may coexist in a particular media discourse about politics, serving different rhetorical purposes in different situational circumstances. Also, they should be seen not just as contributing to the formation of citizens' personal 'attitudes' about politics but also as generative meaning practices, which result in different conceptualizations of the possibilities and limits of political action.

As already mentioned, discourse psychology takes no particular interest in the media. However, Potter's comprehensive analysis of the situational construction of facticity is full of examples from media discourses, as he demonstrates how speakers in news programs take great pains verbally to demonstrate that they do not 'have an axe to grind,' to

voluntarily confess to having a stake in some state of affairs in order to create an impression of honesty and trustworthiness despite their stake, to claim that "facts show that . . ." something is the case, to bolster credibility by adducing the testimony of sources whose identity may be difficult to establish (e.g., when news reports draw on so-called 'community sources' for their reporting of city gang warfare), and so on.

The most interesting and systematic work on media discourses from a situational perspective of dynamic interpersonal negotiation, however, has come from scholars who view themselves as conversation analysts rather than discourse psychologists (Clayman and Heritage, 2002; Greatbatch, 1998; Heritage and Greatbatch, 1991). One growing body of work has analyzed the most interactive genre of news production, the news interview (*see* **Conversation Analysis**).

In such studies, there is not much interest in the possible ideological meanings of the sequence of utterances. Attention is focused on the interactive dynamics of the interview exchanges as their turn-taking patterns are compared with those of ordinary everyday conversation in order to illuminate the specific constraints and options that govern the situational production of such interviews within the framework of public service broadcasting.

Noting that news interviews deviate systematically from ordinary conversation in replacing the latter's question–answer–receipt pattern with a question–answer–question sequence, Heritage (1985) explained this difference by the fact that news interviews are produced for an overhearing audience. By avoiding the evaluation inherent in the third-turn 'receipt'–response characteristic of normal conversation, the interviewer declines the role of evaluating answer recipient while maintaining the neutral role of answer elicitor.

The importance of the overhearing audience also manifests itself in the frequent occurrence of so-called 'formulating' utterances, in which an interviewer (by saying to the interviewee, "So you're suggesting that . . .") may make explicit the potentially controversial implications of a politician's answer while merely appearing to rephrase what the interviewee just said. Formulations may thus also serve an important function within the institutional framework of public service broadcasting, which requires journalists to maintain impartiality and balance in the coverage of controversial matters.

A completely different type of TV interaction for an overhearing audience is analyzed by Crow (1986), who explores the conversational pragmatics of a U.S. phone-in program in which a sexologist host gives advice about sexual problems, a genre that falls between private interpersonal talk and talk explicitly designed for an overhearing audience. Montgomery (1986) offers an excellent example of the analysis of broadcast monologue as he demonstrates how radio DJ talk, in contrast to third-person-based radio news monologue, operates on the axis between first and second person pronominal address. The DJ constructs an imagined community with his or her listeners in a simulated half-dialogue in which he or she does not display the slightest sign of awkwardness that his or her initiating speech acts (e.g., greetings and questions) are not responded to by anybody. Scannell (1991) presented a diverse range of studies on different types of conversational interaction in the broadcast media (*see* **Talk Shows**).

Analyzing the Visual Aspects of Media Discourse

The visual aspects of modern media discourses have presented a difficult challenge for analysts of mediated meaning processes for many years. It is characteristic of discourse analytical approaches that they are almost exclusively focused on media language, whereas the visual dimensions of news reports in print and electronic media are at best given secondary attention.

This situation exists despite the fact that it has long since become conventional wisdom for media research that the media landscape is increasingly dominated by still and moving pictures, which carry a substantial part of the total meaning communicated in newspapers and magazines, on television, and in the new media.

When visual analysis of media pictures is attempted, the analytical tools always derive from the same two sources: Roland Barthes's operationalization of the linguistic concepts of denotation and connotation for the analysis of images, especially photographs (*see* **Barthes, Roland (1915–1980)**), and semiotician Charles S. Peirce's concepts of iconic, indexical, and symbolic signs (for a detailed analysis of news photographs, see Hall (1973) and Fiske (1990).

Barthes (1964) suggested that we distinguish between two orders of meaning in a photograph: the denotative level, which carries the innocent, factual meanings available to any observer irrespective of cultural background, and the connotative level, which carries the visual meanings that a specific culture assigns to the denotative message.

Barthes's original example presented an advertisement that denotatively pictures a string shopping bag

in which one can see some onions, a green pepper, a can of tomato sauce, and two packets of pasta; the colors are yellow and green on a red background. In the French context of Barthes's analysis, this visual message acquires the cultural meaning (connotation) of 'Italianicity,' and as a selling proposition the ad offers not just a number of unrelated products but the whole atmosphere associated with Italian cuisine. In similar fashion, other ads may offer visually based connotations such as sexuality, family happiness, scientific progress, and historical authenticity. According to Barthes, these connotative meanings will appear to the consumer as naturally given, not as ideological constructs, because they are 'grafted' onto the underlying, innocent denotative meaning. In this way, advertisers and other message senders may use connotations to convey taken-for-granted meanings that are shared within a culture without making these (ideological) meanings available for critical scrutiny.

The analytical terms borrowed from Peircean semiotics have to do with the relations between signs and the real-world objects to which they refer (Peirce, 1985). Whereas a 'symbol' is a sign whose connection with its object is purely a matter of convention (the linguistic 'word' being the obvious example), an 'icon' is a sign that is related to its referent through similarity; thus, a photograph in a news article or in an advertisement is an iconic sign of the real-world phenomenon it represents. An 'index' is a sign that signifies by existential or physical connection with its object, such as when a product advertised in a magazine ad is made visually contiguous to the paraphernalia of a desirable lifestyle, whose qualities may thereby become associated with the product.

It should be stressed that the three Peircean concepts are not to be thought of as three different kinds of sign but, rather, as three dimensions that are inherent properties of all signs in relation to their referents. A media picture of the White House is thus simultaneously an iconic representation of a particular building located in Washington, DC; an indexical representation of the government of the United States since it houses and thereby stands for its primary executive officer; and a symbolic representation of the connotative values conventionally associated with the United States and its president, be they those of the coercive global policeman or the home of freedom and democracy.

It is especially the indexical/metonymical aspects of visual signs that may carry powerful ideological implications because they seem to establish a natural connection between the sign and its referent, between the 'part' that is selected by the photographer or editor for visual representation in the news photo and the 'whole' scene that the photo supposedly represents. Thus, a metonymic photograph of a single violent incident may convey a wrong impression of a demonstration that was otherwise peaceful and orderly (*see* **Pragmatic Indexing**).

These semiotic tools have proved to be of considerable heuristic value for the analysis of media images, but it must be acknowledged that they have been unable to provide insights beyond the commonsensical. Moreover, the distinction between denotation and connotation is theoretically dubious because it is impossible within the terms of the theory to define precisely the threshold between noncultural and culturally invested meaning on which the distinction relies (Eco, 1968). Some attempts have been made in recent years to change these theoretical terms by drawing on a cognitive approach to visual perception, according to which there is no fundamental difference between the perceptual processes of making sense of real-world and pictorial visual stimuli. The first-order visual media meanings are naturally perceived by the visual sense and then enter into a process of cultural investment and interpretation according to conventionalized signifying processes (Messaris, 1997).

The challenge of developing an innovative approach to the analysis of visual discourse has been taken up by scholars who wish to take discourse analysis much further than merely extending its field of operation from linguistic to also include visual signs. They suggest that the modern media from school textbooks to the World Wide Web are increasingly producing texts that are multimodal, making use of a range of representational and communicational modes within the limits of one text (Kress and van Leeuwen, 2001).

The range of the different 'modes' of communication includes, in addition to verbal language, the visual (including graphic styles, spatial display, diagrams, pictures from line drawings, and still and moving photos), the gestural, sound, etc. and requires the building of a comprehensive 'discourse semiotic' in which all kinds of human semiosis are explored within the terms of one theoretical platform (Kress *et al.*, 1997: 258):

> Discourse analysis has, on the whole, focused on the linguistically realized text. In the multimodal approach the attempt is to understand all the representational modes which are in play in the text, in the same degree of detail and with the same methodological precision as discourse analysis is able to do with linguistic text.

The overall theoretical framework of Kress and van Leeuwen's visual discourse semiotics is strongly akin to Fairclough's three-dimensional model, whereas the analytical practice is inspired eclectically by theoretical and analytical work in linguistics, visual

semiotics, film theory, art criticism, as well as numerous predecessors in the various fields of media research, especially the analysis of advertising (Cook, 1992; Myers, 1994; Williamson, 1978).

At this stage, however, it is not evident that the multimodal approach represents the kind of genuine innovation of the analysis of visual media discourses claimed by the authors. First, irrespective of the authors' protestations to the contrary, with its indebtedness to Halliday's (1978) theory of social semiotics, the approach is based on and to some extent biased toward a linguistic conceptualization of the other modes of representation. Moreover, both some of its theoretical ground pillars and some of the analytical insights balance somewhat uneasily between the postulatory and the commonsensical, and the analytical conclusions sometimes lapse into a simplistic view of the transfer of ideology from verbal–visual text to reader.

Toward a Pragmatics of Media

This article has argued that a holistic theoretical perspective is necessary to understand the way the media communicate with citizens and consumers living in a mediatized world. One consequence of the adoption of a holistic, discourse–analytical perspective on the media is that in addition to focusing the analytical spotlight on the textual meaning processes in the media, the analyst is also invited to explore the discursive practices through which media texts are produced and received, as well as the larger sociocultural framework within which these processes take place. This requires the analyst to supplement traditional forms of critical analysis of media texts with ethnography-inspired interview-based fieldwork of, for instance, journalistic production routines and audience reception processes.

Such discourse–ethnographic work produces new textual objects of analysis in the form of qualitative interviews with media producers and audience members about the meaning processes they engage in around the media product (Lindlof, 1995). Clearly, this research agenda is no less imbued with theoretical and methodological hazards than that of traditional media language analysis, which may explain the reluctance of media discourse analysts to embark on the kind of ethnographic fieldwork that they readily acknowledge is necessary. However, the payoff in terms of explanatory power is evident in those few instances in which scholars have faced the holistic challenge and brought together insights from production, textual, and reception studies of mediated communication (Deacon *et al.*, 1999).

Introduction

Although it might sound trivial, it is nevertheless true that our everyday life is increasingly perfused, guided, and even structured by media and media products/messages. In order to cope with the media messages as such and with the changing variety of media we encounter – from newspapers and magazines to virtual reality environs, from movies and television shows to the Internet – we are in need of an integrated theory and models to analyze that are appropriate to handle the messages both theoretically and in practice. It is most likely that whoever is dealing with media messages – from high school students or laypersons to academics or media professionals – will sooner or later stumble upon the notion 'media semiotics,' and subsequently try to get further information.

Media Semiotics and/or Medium in Semiotic Handbooks – A First Glimpse

Usually, a first approach to a topic is to look up it up either in printed sources or in the more recent and increasingly popular way to get information, the

Media: Semiotics

G Withalm, University of Applied Arts, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Although it might sound trivial, it is nevertheless true that our everyday life is increasingly perfused, guided, and even structured by media and media products/messages. In order to cope with the media messages as such and with the changing variety of media we encounter – from newspapers and magazines to virtual reality environs, from movies and television shows to the Internet – we are in need of an integrated theory and models to analyze that are appropriate to handle the messages both theoretically and in practice. It is most likely that whoever is dealing with media messages – from high school students or laypersons to academics or media professionals – will sooner or later stumble upon the notion 'media semiotics,' and subsequently try to get further information.

Media Semiotics and/or Medium in Semiotic Handbooks – A First Glimpse

Usually, a first approach to a topic is to look up it up either in printed sources or in the more recent and increasingly popular way to get information, the

Internet. A quick Web search with the two keywords 'media' and 'semiotics' renders more than 83 000 results (almost a moderate figure compared to some 328 000 results in the case of a search for 'semiotics' alone). After a first glance, however, the number will diminish drastically, since the majority of the first some 50 entries (normally checked) refer either to the few books that have the words 'media semiotics' in the title, or to Web pages offering sort of directories with links to ever the same handful of sites. So the reader seeking for information will certainly return to more conservative sources, that is, printed material, and she/he will look up the entries in diverse dictionaries and encyclopedias, and the respective articles on medium, media studies, or media semiotics in introductory works.

Apart from the desired first information, such texts can also show whether the field in question, in our case: media semiotics, is recognized and appreciated as an individual area of semiotic research, or, more generally, whether it is present at all in the consulted texts, and how the topic is dealt with in the pertinent literature.

Unfortunately, looking for definitions of, or at least descriptive passages about, media semiotics as a distinct field of semiotic research, analyses, and theorizing will not bring much help for the inquisitive novice, since the search does not render the expected results. A switch to the search for 'medium' or 'media' is, again, not very promising. The reason for this lack of entries, however, is definitely not caused by a lack of interest of semioticians in the field covered, or, even worse, a neglect of the notion as somewhat irrelevant to semiotics. For this observation, an explanation can be offered that lies in the comparably late process of academic autonomy and independence. Like all disciplines, or even subdisciplines and paradigms, semiotics has its own set of notions, the definitions of which sometimes overlap and coincide with those found in neighboring and adjacent disciplines; in other cases, they differ extremely from those generally known. To construct a concise terminological building in its own right, semiotic dictionaries and handbooks have to concentrate on the core terms. Although the process of mediation is by definition fundamental to semiotics and thus a pivotal area of semiotic reasoning, a crucial topic of semiotic research, and despite the interest in the field and the wide-spread use of the notion, 'medium' as such is not a genuinely semiotic concept.

How is 'media semiotics' (or, more generally, medium) dealt with in some of the standard reference works published in the last two decades?

One of the handbooks to start with for an in-depth look at notions and concepts is certainly the three-volume *Encyclopedic dictionary of semiotics* (edited by the long-term editor-in-chief of the journal *Semiotica*, the late Thomas A. Sebeok, and first published in 1986). The second volume contains an article titled 'Medium.' Unfortunately, the one-and-a-half pages give no information whatsoever on medium, let alone media semiotics, since they are dealing with nothing but the notion referred to in the subtitle: 'Message.' This focus is somehow strange as there is another entry explicitly titled 'Message/Medium' that in turn discusses nothing but Marshall McLuhan's view of the 'medium/message' complementarity.

Although small in size, Vincent Colapietro's *Glossary of semiotics* (1993), is usually a good spot for a first check on notions. With regard to our subject, the reader is less successful since the book has not a single entry on medium or media, let alone on media semiotics.

The index to the first 100 volumes of *Semiotica*, published 1969–1994, offers a 'Subject Index: Scientific Fields' that, although quite detailed, does not even list the category keyword 'medium' or 'media' (1997). Looking more closely through the list of fields reveals, however, that the observation must not be read as a lack of papers on media topics: there are 2 articles subsumed under the heading 'communication,' 28 under 'cinema,' some 40 more under 'film.'

With the 1998 *Encyclopedia of semiotics* (edited by Paul Bouissac), it is quite the same at first sight: the reader will not find an individual article on medium or media. Thanks to the index, he or she can check other entries to find something on the 'ideological role of media,' on 'transformations,' 'violence,' and 'women in media.' In addition, media is generally crossreferenced to mass communication, which has an entry. Further articles are dealing with 'semiotics of advertising,' cartoons, cinema, comics, communication, computer and computer-mediated communication, film semiotics (plus additional entries on: *grande syntagmatique*, imaginary signifier, and Christian Metz), mass communication, photography, and pictorial semiotics (1998).

Like all the other volumes, the 2000 *Encyclopedic dictionary of semiotics, media and communications* (edited by Marcel Danesi) has no description of the field of media semiotics, but, of course, it includes an entry on medium that will be discussed below, since it offers a concise definition of, and approach to, the notion (2000).

Winfried Nöth's *Handbuch der Semiotik* was first published in 1985 in German; in 1990, a heavily revised English version, the *Handbook of semiotics*, appeared, which was the basis for the 2000, second German edition. The 1990 English version grouped several chapters dealing with topics usually

subsumed under 'media' under the heading 'Aesthetics and visual communication.' The second German edition features a new chapter, explicitly titled '*Mediensemiotik*.' The areas presented are: media, image, image and text, maps, comics, photography, film, and advertising. The subject index, however, enumerates several other instances where the notion media is discussed. Taking up ideas first presented in his introductory contributions to two collective volumes (Nöth, 1997, 1998), Nöth started his chapter on 'media' with some general observations on the relationship between semiotics and the media, naming both early examples of semiotic studies of media texts and several strains and ideas within semiotics adopted for media studies. He then continued with three subchapters dealing with: 'themes of media semiotics,' 'signs, medium and the media,' and 'signs, reality and hyper reality.'

So far the largest (and most recent) reference work is *Semiotik: Ein Handbuch zu den zeichentheoretischen Grundlagen von Natur und Kultur/Semiotics: a handbook on the sign-theoretic foundations of nature and culture* (referred to hence as *Semiotik/Semiotics*), edited by Roland Posner, the former President of the International Association for Semiotic Studies IASS-AIS. Due to the structure of the handbook, the central article on our topic in volume 3 has the term in question – media semiotics – only in the subtitle (and unlike 'semiotics of culture' or 'cultural semiotics,' it is not listed in the index either). However, the text on 'Semiotic aspects of mass media studies: media semiotics' (Wolf, 2003) gave a good overview on the relationship between the two adjacent, or even overlapping, fields. Starting from the history of mass media studies, Wolf continued to outline the main areas of mass media research, and recent trends. When it came to the actual relationship, he proceeded from a strong focus on Eco's theoretical models of the code, as well as the discussion of the reciprocal expectations and changing semiotic paradigms to the interconnection between semiotics and British cultural studies. The last part showed "thematic areas where integration between semiotics and mass media studies is more advanced and is required by the media under examination" (Wolf, 2003: 2932), like the "textual structures and utterance processes," or "cognitive activities of the media audience" (Wolf, 2003: 2933). Wolf ended with "open questions on the research agenda" (Wolf, 2003: 2934), which will be presented later on.

Within the same chapter of the third volume of *Semiotik/Semiotics*, presenting the relations between semiotics and individual disciplines, there is also a contribution on '*Semiotische Aspekte der Filmwissenschaft: Filmsemiotik*' ('semiotic aspects of film studies: semiotics of the cinema,' Kloepfer, 2003). Concerning 'medium' the handbook contains several articles that mention the notion even in the title. Chapter 2 of the first volume, for instance, is already titled 'Aspects of semiosis – channels, media, and codes,' and among others it features '*Technische Medien der Semiose*' ('Technical media in semiosis,' Böhme-Dürr, 1997), and 'Social media of semiosis' (Threadgold, 1997). At the end, in volume 4, which offers a chapter on selected topics of semiotics, there is also an article on '*Multimediale Kommunikation*' ('Multimedia communication'; Hess-Lüttich and Schmauks, 2004). Thanks to the detailed index of subjects the reader is able to look up some further contributions where medium or media are discussed.

Finally, as already mentioned in the very first paragraphs, there are some textbooks, introductory works, collective volumes, or chapters in more general overviews of semiotic studies that carry the formula 'media semiotics' in their title. The earliest coupling was, most probably, a German collective volume edited by Günter Bentele in 1981, titled *Semiotik und Massenmedien*. The various articles focused on different media and the analyses of media texts. Approximately a decade later, Ernest W. B. Hess-Lüttich (1990a) dealt with '*Massenmedien und Semiotik*' in the context of semiotics in the individual sciences.

A volume that focused entirely on this field was certainly *Semiotics of the media. state of the art, projects, and perspectives*, edited by Winfried Nöth (1997), which contained a large number of papers presented in Kassel at the 1995 conference on the semiotics of media.

Finally, two more introductory publications are *Media semiotics: an introduction* (Bignell, 1997) and *Understanding media semiotics* (Danesi, 2002). In the latter volume, the field is defined in a first approach in the following way:

> The primary object of media semiotics is to study how the mass media create or recycle signs for their own ends. It does so [...] by asking: (1) what something means or represents, (2) how it exemplifies its meaning, and (3) why it has the meaning that it has (Danesi, 2002: 34).

The restriction to the explicit naming of semiotics in the title, however, might exclude several publications that proceed from semiotic concepts without telling so, like, a collection of early papers from the Birmingham Centre for Contemporary Cultural Studies (Hall *et al.*, 1980). The same applies to volumes on special topics, as for instance, narrativity, edited or written by semioticians (cf. Kloepfer and Möller, 1986; Cobley, 2001).

Semiotics of the Media and/or Media Semiotics

What most semioticians seem to agree upon is the view that there is nothing like a unified media semiotic approach (cf. Bentele, 1981: 26; Hess-Lüttich, 1990a: 177; Nöth, 1997: 1); the more so since, on the one hand, media studies themselves have to be considered rather a vast field of research than a single discipline, and on the other hand, semiotics cannot be regarded as a unified single paradigm discipline either. As will be shown in several other entries (*see* **Paris School Semiotics**), the semiotic enterprise is made up of different schools and traditions, starting from the big divide between the philosophic or Peircean or American line of triadic concepts of semiosis and the linguistic or Saussurean or continental line of binary sign models. Evidently, these two and many other semiotic models and theories found their way into the study of media.

Of particular interest for both disciplines seems to be the special kind of relationship between semiotics and media studies. As will be shown below, the history of semiotic studies of media and media texts goes at least back to the 1960s, which means that semiotics has been there long before the media studies hype has commenced. Nonetheless, semiotics has not always been valued as an approach fruitful for media studies (or at least not all over the world).

Rereading the various introductory texts on media semiotics written over some two decades also reveals how the relation has changed during the last years.

Hess-Lüttich (1990a) observed a certain skeptical attitude toward semiotics among the various disciplines that share the research object 'mass media':

> Zu sehr sind die Medienforscher noch ihren jeweiligen Fachtraditionen verpflichtet und verhaftet, als daß sie die integrierende Kraft semiotischer Theorienbildung methodisch zu nutzen gelernt hätten. In Literaturwissenschaft wie Publizistik wird gegen die Semiotik zuweilen als 'Mode' polemisiert, ihre zweitausendjährige Geschichte verkennend (Hess-Lüttich, 1990a: 203).

In the mid-1990s, Nöth discussed the range in the geographical distribution of media semiotics:

> While in countries like Italy (especially under the influence of Umberto Eco), France, Spain, and Brazil, the terms 'semiotics' and 'media studies' are often almost used synonymously, in Germany and in the English speaking countries, the semiotics of the media has been considered as less central in media studies (Nöth, 1997: 6–7).

One specific area, however, deserves a separate discussion: British cultural studies that to a large degree focus on media and are rooted in semiotics. As a more general observation, it seems that in the last years semiotics has finally found its way into general media and communication studies, as university curricula, reading lists, and undergraduate text books can show.

Depending whether viewed from the side of semiotics or from that of media studies, the question which of the two is considered just an auxiliary discipline or method, and questions of dominance and subordinance are answered quite controversially. Winfried Nöth titled his contribution in the 1998 volume even '*Die Semiotik als Medienwissenschaft*' (or 'Semiotics as a media science par excellence' as he named the relation in his introduction to *Semiotics of the media* Nöth, 1997: 5), and considered semiotics to be the fundamental discipline for media studies. Accordingly, his enumeration of topics dealt with in media semiotics is by far the most comprehensive, and almost coextensive with that of semiotics in general, since it comprises themes like:

> Kommunikation, Kognition und Emotion, Mediensemiose und «Realität», Referenz und Selbstreferentialität, Wahrheit, Mythos und Ideologie, Information, «Objektivität» oder Manipulation und schliesslich auch die evolutionsgeschichtlichen Wurzeln der Zeichenproduktion und -rezeption in den Medien (Nöth, 1998: 53).

Although generally used in a synonymous way, the two different notions in the section heading could discern two fields. Analogous to the distinction between semiotics of culture and cultural semiotics, the semiotically rooted occupation with the media goes in two directions: (1) the semiotic exploration of media genres and texts (or, how semiotics can be used for the analysis of movies, ads, or newspapers, as it is sometimes stated in media studies textbooks); and (2) a semiotic theory of (mass) communication and media. Both in general recognition and in the literature, the first one is by far more present and touches each and every mass medium used, from the more traditional ones to latest electronic developments in information and communication technologies. Nevertheless, it is exactly the latter field in which the modeling and conceptual quality of semiotics is able to contribute to the further development of media studies: semiotics is not just another discipline dealing with a particular object (which in the case of semiotics is vast enough: signs and sign processes of all kinds), but it is always and at the same time a metadiscipline reflecting on concepts, paradigms, and approaches. In this sense, media semiotics is not only reflecting on media and media texts, but it is also able to offer the forum for the dialogue between media studies and semiotics and to cogitate on their relation and their tasks.

Semiotics and (Mass) Communication Processes

The relation between semiotics and both communication studies and media studies is rather intricate. In order to discuss the role of semiotic studies and models with regard to media (studies), the reflection on a common topic could be an appropriate point of departure: the communication process.

Since it is generally agreed upon that, as Jakobson has put it, "[t]he subject matter of semiotic is the communication of any messages whatever" (Jakobson, 1973: 32), semiotics and communication/media studies are neighboring disciplines that share a research object: communication (*see* **Communication: Semiotic Approaches**), although semiotics cannot be reduced to the study of communication, because it is equally concerned with signification (cf. Prieto, 1968; Mounin, 1970), or significative and cognitive processes (cf. Nöth, 1985: 235). Krampen made yet another clarification concerning the particular relation between communication and semiosis that is needful:

> A communication process in which a sender transmits second hand experiences to a receiver is a sign process **par excellence**. In this sense, models of communication processes are always models of semioses, but not **vice versa** (Krampen, 1997a).

Accordingly, reflections on communication are often present when semioticians talk about sign processes. One of these authors for whom communication is a central concept is Charles W. Morris (1946). Alongside the divide between communication and signification, Umberto Eco offers a discussion on communication in his *Trattato di semiotica generale* (1975).

Models and Concepts

The preoccupation of semiotics with communicative processes is not a recent phenomenon and can look back at least on more than one hundred years of history (if the two and a half millennia of occidental history of dealing with semiotic questions at large is not taken into account!).

Decades before Shannon and Weaver formulated their communication model with sender and receiver in 1949, Ferdinand de Saussure (1916) (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**) presented his view on the communicative situation (i.e., the speech circuit model) that, contrary to the 1940s diagram, implied already the three fundamental dimensions: the semantic dimension or the constitution of meaning, the pragmatic dimension showing sign producers in action, and the dialogic dimension of message exchange. Unfortunately, the speech circuit model was hidden within Saussure's courses on linguistics and hardly received outside this discipline. Communication studies would have started differently, if the ruling paradigm would have come from semiology. Although they have envisaged a broader application of their information–theoretic model, the two authors are not to blame for the development in the 1950s and 1960s and the resulting lack of a semantic and a pragmatic focus, since they created the model for a specific purpose and never dealt with semantic aspects of the message. The problem lies rather in those followers who eagerly took the model as a ready-made device and insufficiently adopted it for human communication. As a consequence, generations of students in communication and media studies were treated with technicistic concepts based on the short-sighted transmission model of communication.

Ferdinand de Saussure's diagram might have been the first semiotic model of communication, but it is definitely not the only one. Since semiotics is not a single-approach enterprise, but, as mentioned above, consists of several different currents, there is also more than one model of the communication process or of the sign process, of 'semiosis,' to use a more general term. (An extensive discussion of the diverse views of semiosis as well as a complex and comprehensive semiosic matrix is presented in Krampen, 1997a; cf. also Krampen, 1997b.)

Chronologically, the next diagrammatic formulation that has to be taken into consideration for the study of communication was developed by Karl Bühler (*see* **Bühler, Karl (1879–1963)**). In the 1930s, his tripartite organon model of language (1934: 28) has the sign as the center and point of intersection between three elements, the three respective functions of the sign with regard to these elements and the three correlated sign moments: the sender (*Ausdrucksfunktion* or the expressive function; symptom or index), the receiver (*Appellfunktion* or the appellative or conative function; signal), and the objects or states of affairs (*Darstellungsfunktion* or referential/representational function; symbol).

Bühler's schema has to be mentioned, although its reception was still restricted to linguistics, since it was quite influential for another concept that, in turn, has found its way into media and communication studies: Roman Jakobson's communication model (*see* **Jakobson, Roman (1896–1982)**).

Jakobson proceeded from Karl Bühler's organon model of language and extended it to a schema combining six constitutive factors of communication, which are paired with six equivalent functions (named in parentheses): addresser (emotive), message (poetic), addressee (conative), context (referential), contact (phatic), and code (metalinguistic).

Although the schema seems to be similar to the standard one-way model of communication between a sender and a receiver (in particular in the graphic presentation), there is a fundamental difference with regard to the elements due to including the context and the code. Originally conceived for verbal communication, Roman Jakobson's model of these six "factors inalienably involved" (Jakobson, 1960: 353) has been adopted for the analysis of nonverbal communicative and media processes. Looking through the publications, the application to domains as different as architecture and advertising can be found. The most recent example is the discussion of Jakobson's concepts with regard to new media and multiagent environments (Petric *et al.*, 2001). Relying on the systemic quality of Jakobson's thinking, Itamar Even-Zohar adapted the schema to the literary (poly)system (cf. Even-Zohar, 1990: 31), which could be considered to be just a special case of media systems in general.

It seems that over the years communication studies has developed a strong tendency to deal with aspects that are clearly associated with semiotics. According to Berger and Chaffee,

> communication science seeks to understand the production, processing, and effects of symbol and signal systems by developing testable theories, containing lawful generalizations, that explain phenomena associated with the production, processing, and effects (Berger and Chaffee, 1987: 17).

Despite the wording (and the concepts referred to), the way scholars in communication science intended to handle the topic is again not a qualitative one, but rather aimed at empiricist approaches delivering quantifiable results. From the side of semiotically oriented researchers, however, this attitude is described quite differently, even if they proceed from the same observation, thus preparing the ground for a sign–theoretic foundation of the study of communication processes. In his article in *Semiotik/Semiotics* on semiotic aspects of mass media studies, Mauro Wolf stated:

> Indeed, there was a strong need in communication studies to focus on the complex nature of the communicative process, and semiotics was better suited than psychology or sociology to understand this element of crucial relevance in mass communication processes (Wolf, 2003: 2930).

As already shown, what semiotics can indeed offer is a differentiated view of the communication process as sign process.

Looking through the many definitions of communication to be found in the various encyclopedias, glossaries, and textbooks, we can see that many scholars in communication studies include signs and sign production in their formulas. Accordingly, the focus on Man as a producer and recipient (or reproducer) of the message, which is necessarily and always conveyed in form of sign vehicles or signifiers or representamina or signantia (depending on the semiotic theory adopted), is no longer mistaken for a restriction since it includes per definition an antireductionist approach compared to shortsighted technicistic models. The view of communication as semiosis is not confined to only meaning-oriented considerations as opposed to society-oriented approaches, because in semiosis three moments are interconnected: the production/constitution of meaning (semantic dimension); the structure of the message (syntactic dimension); and the usage of the message including attitudes and actions resulting thereof (pragmatic dimension). The most explicit integration of social aspects can be found in Ferruccio Rossi-Landi's sociosemiotic theory of social reproduction in which communication is defined as sign exchange. For Rossi-Landi, social reproduction always comprehends "three indissoluble correlated moments": production–exchange–consumption. Exchange "is always, at the same time and constitutively, external material exchange [and] sign exchange, that is communication, including as such within it: **sign production**, **sign exchange** in the strict sense, and **sign consumption**" (Rossi-Landi, 1975: 65; cf. 1985: 38).

Different Areas of Communication

The study of communication is confronted with a vast field of quite different types of communication, or communicative situations, with quite different means of communication involved and used to convey messages and meaning.

Due to the importance of the sign system language, there can hardly be an analysis of verbal communication without semiolinguistic concepts, starting from the situation, the course of the conversation, the various registers used, or the content of the utterance.

In much the same way, a great deal of the publications on nonverbal communication is based within semiotics, like the research on 'body language' or proxemics.

As soon as we transcend the domain of communication between human beings and turn to man–machine–communication, we have to consider intricate relations and overlaps between semiotics and cognitive sciences or AI-research respectively.

With the area of mass communication, finally, we enter the diffusion zone between communication and media studies. Looking at the various subfields of mass communication research, additional connections

can be found, like the transition from research on subconscious effects to the occupation with the recipients' competence in handling mass media. From the point of view of semiotics, processes of mass communication are also semiosic processes like any other communication. When split into the partial processes involved and analyzed in detail, however, the degree of complexity appears to be much higher. Krampen distinguishes the subsequent and simultaneous phases and the various channels used, and he concludes that

> a mass communication event is a supersemiosis Σ constituting a matrix of semioses Z, modeled by semiosic matrices, with n kinds of channels [...] during m kinds of stages in the production of a mass communication event (e.g., acquitisition, editing, elaborating, sequencing or layout, sending or printing, etc.) (Krampen, 1997b: 96).

As discussed above, the question of the proportion of semiotic theories and analyses within media studies proper, or the specific relation of the two disciplines, can only be answered after a closer look at the entirety of semiotic approaches (including closely related concepts), their respective historic influence (cf. Wolf, 2003).

Notions and Concepts

Medium and Media

Even though 'medium' is not part of the set of semiotic notions proper, it is widely used also within semiotic texts and thus deserves some attention, the more so, since one of the tasks semiotics is specially apt for is the theoretic reflection and a systematic reconsideration of pivotal concepts and models in media studies, like channel or medium (cf. Wulff, 1978).

Since several different disciplines are occupied with the study of media, media texts, media institutions, etc., the notion of medium is in itself an iridescent notion. Unfortunately, the degree of usage in communication and media studies does not always correspond to that of pertinent definitions of the notion. In his entry on 'Multimedia communication' in Sebeok's *Encyclopedic dictionary of semiotics*, Hess-Lüttich thematized this problem:

> Medium's widespread usage in mass communication and psychology, in economics and cybernetics, in physics and philology, makes it difficult to agree on an integrated basis for founding a category of material transmission of social meaning (Hess-Lüttich, 1986: 574).

More often than not, apart from the general quoting of the Latin origin of the term (*medius* 'between, the middle'), the solution offered by the authors seems to be rather a description resorting to everyday experiences (and uses) of the term and the enumeration of examples than a definition *sensu stricto*. Texts that try to cope with the term 'medium' usually start from the physical meaning of the word (that is, the contact matter or physical substance), only to add in the next sentences that it is generally used for the means of communication.

An example for the contextually explicable restriction to the latter can be found in the 'Glossary' for the first Elsevier *Encyclopedia of language and linguistics* (ELL1), which names two definitions: "1 The means used in a communication, i.e., whether it is spoken, written, symbolic, color coded, etc., e.g., phonic, aural, visual medium. 2 A channel of communication as in mass media" (1994: 5144–5145). Mass media in turn are defined as "(t)he (mass produced) media (see medium 2) which seek to communicate with a mass audience, e.g., television, newspapers" (1994: 5144).

A widespread classificatory approach distinguishes between primary media (which are entirely based on the abilities of our body and function without technical equipments), secondary media (the sender uses some kind of machines), and tertiary media (both sender and receiver have to rely on technical equipment) (cf. Pross, 1972); recently, the tripartite scheme has been augmented by a quaternary type, which comprise the digital media.

Another tripartite scheme is elaborated by Marcel Danesi in his *Encyclopedic dictionary of semiotics, media and communications*. He opened the entry with general definitions: "1. any means, agency, or instrument of communication; 2. the physical means by which a sign or text is encoded (put together) and through which it is transmitted (delivered, actualized)" (Danesi, 2000: 141–142). In the added explanatory notes, he then proceeded from prewriting media for communication (oral–auditory and pictographic), and discussed the alphabet in terms of a Kuhnian paradigm shift. After briefly discussing McLuhan, and describing how each medium implicates knowledge of specific kinds of codes that the medium itself determined to be deployed, Danesi offered three more entries on three different types of medium (and the respective examples) that should be distinguished in the analysis. (1) The artifactual medium: "artifactual means or mode of encoding and decoding a message," like books, paintings, sculptures, or letters; (2) the mechanical medium: "mechanical means or mode of transmitting a message," that is, telephones, radios, television sets, computers, videos; and (3) the natural medium: "natural means or mode of encoding and decoding a message," like the voice (speech), the face (expressions), the body (gesture, posture, etc.) (Danesi, 2000: 142).

Despite such differentiated views, today the notion of medium is often used just in the plural and thus confined to denominate the means of mass communication. One of these definitions of mass media is included in the entry on mass communication of the 1998 *Encyclopedia of semiotics*, considering them to be

> channels of communication, located at the institutional and corporate levels of society that use large-scale high-technology methods to supply standardized communication products to widespread heterogeneous audiences (Fulton, 1998: 389).

In somehow wider descriptions, the concept of (mass) media includes such different instances of the communication or sign process as the channel (and thus also the physical substrate used for transmission), the entire apparatus, the sender (often in the form of an organization or institution), the codes, and the signs (and sign systems) used. According to such a multifaceted view, Karin Böhme-Dürr defines medium in her *Semiotik/Semiotics* article on technical media in the following way:

> Der Begriff 'Medium' bezieht sich [...] auf **Kommunikations**mittel, also auf die Mittel zur Weitergabe von Zeichen. Kommunikationsmittel sind zum einen technische Geräte (Instrumente, Apparate) und zum anderen Zeichenkörper (=Zeichenträger) (Böhme-Dürr, 1997: 358).

To make this somehow very general definition operational, she distinguished three clusters conforming to the various disciplines dealing with it: the concept of media as used (1) in the social sciences, (2) the natural sciences, and (3) the technological media concept (cf. Böhme-Dürr, 1997: 358).

The most differentiated classificatory grid of subconceptions is offered by Roland Posner. Proceeding from the actual use of the notion both in everyday language and in the pertinent literature, he distinguished six different uses of the notion medium based on the kind of sign processes involved: (1) the biological concept, which characterizes the sign systems according to the body organs and sense modalities involved in production, distribution, and reception of signs (eyes/visual media; ears/auditive media; nose/olfactory media; taste/gustatory media; skin/tactile media); (2) the physical concept, which characterizes the sign systems based on the chemical elements and the physical conditions; (3) the technological concept, based on the technical means and apparatuses used; (4) the sociological concept, covering social institutions that organize the biological, physical, and technical means; (5) the culture-related concept, which characterizes the sign systems according to the aims of the messages conveyed by them; and (6) the code-related concept, which characterizes the sign systems according to the rules to correlate messages and sign vehicles (Posner, 1985: 255–257). On the one hand, this plurality of concepts is only helpful when the various notions and the correlated media concepts and criteria are kept apart for the sake of precision and clarity. On the other hand, it has to be clear that the differentiation of these six media conceptions is only made for analytical reasons; with regard to the actual process, they have to be viewed together, since they appear simultaneously or consecutively, much in the same way as Krampen has defined the mass communication process as a supersemiosis.

A starting point for a truly semiotic reconsideration of the concept of the medium, however, could be a statement Charles S. Peirce made (presumably in 1905) in which he even equals sign and medium.

"A sign is plainly a species of medium of communication" (Peirce, MS 283, 125). In 1906, he goes one step further and writes: "All my notions are too narrow. Instead of 'Sign,' ought I not to say Medium?" (Peirce, MS 339). With one exception, however, this use did not become the current one. Laying stress on the specific quality of the sign as mediator between object and interpretant, the notion introduced by Max Bense and Elisabeth Walther instead of sign or representamen is *Mittel* or medium. (For her discussion of medium, cf. Walther, 1997.)

A Plethora of Neighboring Notions

'Medium' is not just in itself a multifaceted term. In the pertinent literature, it is always accompanied by several other notions that are only partly core concepts of semiotic theory. Although widely used, 'channel' is one of these notions coming from neighboring disciplines. Originating from information–theoretical texts, it has entered also the (media) semiotic discourses. The problem, however, lies not in the term as such but in a synonymous use of channel and medium (as analyzed in Wulff, 1978), which does not contribute to clarify the various elements and phases of the process. Unfortunately, since all terms in question have diverse meanings, even semioticians are sometimes not very precise in their respective use of the notions. When Thomas A. Sebeok, for instance, discussed how a source is linked with a destination, he described it as "a sort of medium, or channel, a passageway through which the two are capable of establishing and sustaining their communicative exchange" (1991: 27).

Even more complicated is the case with code (*see* **Postmodernism**) that is likewise part and parcel of the terminology in several disciplines dealing with media and communication. 'Code' is often confined

to transformation rules or the rules of correlating the elements of two different systems (the 's-codes' in Eco's terminology). Sometimes a code is regarded as a "set of substitution equations relating significata to signs or signifiers" (Watt and Watt, 1997: 408). Eventually, the term code is often used co-extensive with 'sign repertoire' or even 'sign system,' like for instance in the Jakobson model discussed above.

Although 'sign system' is a central semiotic term, the definitions vary in the different schools and currents. The widest and most fruitful conception of sign system with regard to media semiotics is offered by the Italian semiotician and philosopher Ferruccio Rossi-Landi. In his definition, a sign systems contains

> at least one code, that is the materials on which one works, and the instruments with which one works; [...] the rules to apply the latter on the former [...] the channels and the circumstances that allow communication, the senders and receivers who make use of the code (Rossi-Landi, 1985: 242).

But he goes even one step further when he writes that it

> includes also all the messages which are exchanged or can be exchanged within the universe institutionalized by the the system itself (Rossi-Landi, 1985: 242).

Fields of Media Semiotics

As indicated earlier, semiotics has turned to the study of media texts and contributed its share to their analysis at least since the 1960s. This contribution is evidenced by the remarkable amount of works in applied semiotics that can be subsumed under the heading 'media semiotics.' To establish some kind of order among the hundreds of works related to, and the various ways semioticians are dealing with, the media, two directions can be taken: to follow the usual listing of (mass) media, and to discuss some topics, media semiotics is especially interested in and apt for.

Advertising

From the very beginning, advertising was a preferred area, and the various publications show the variety of semiotic models and concepts that are used to deal with the verbal and visual messages encoded in promotional texts.

Among the most famous papers dealing with print ads is definitely Roland Barthes' (*see* **Barthes, Roland (1915–1980)**) analysis of a French magazine ad for Panzani pasta sauce (1964). Proceeding from the objects depicted (an open string bag with spaghetti packages, a tin of pasta sauce, a sachet of grated parmesan, and assorted fresh vegetables: tomatoes, onions, peppers, a mushroom etc.), he developed the levels of signs involved (fresh products, *italianità*, complete meal, still life, etc.) and the three types of messages: a linguistic, a coded iconic (symbolic), and an noncoded iconic (literal) message. Following the line Barthes opened with the title of this paper, that is 'Rhetoric of the image,' Umberto Eco adapted the classic rhetorical figures to visual texts and used them to analyze advertisements (Eco, 1968). (With regard to rhetorics, the work of the Belgian *Groupe μ* figures among the most prominent) (*see* **Rhetoric: Semiotic Approaches**).

Even though a lot of papers are rooted in the semiologic or semiolinguistic tradition, the Peircean trichotomy of icon, index, and symbol has definitely found its way into the general analytic tool set. Accordingly, the concepts are at the basis of many a publications on posters or print advertisements.

One of the best known theoreticians in the field of advertisement is Jean-Marie Floch who also worked in practice. His analyses of ad messages are based on a complex network of semiotic squares in the Greimasian tradition.

Apart from rhetoric or narrative analyses of ad messages, or those offering critical views concerning the myths and ideologies diffused through ads, there is yet another field of semiotic research and reasoning that is closely related to advertising: marketing and consumer research (cf. Umiker-Sebeok, 1987; Floch, 1990; Mick, 1997) (*see* **Marketing and Semiotics: From Transaction to Relation** and **Brands and Logos**).

Visual Semiotics

Although visual semiotics (Sonesson, 1989) cannot be reduced to media texts in the narrow sense, since works of fine art belong also to the topics investigated, it has to be included in such an overview. There are several groups of visual texts that have a long history of semiotic analysis, like photographs, cartoons, or comics (Eco, 1994) (*see* **Photography: Semiotics** and **Comics: Semiotic Approaches**). One of the classic domains of semiotic investigation are the relations between images and words (the accompanying verbal texts), be it in advertising, graffiti, popular prints, or newspapers (Schnitzer, 1994). For both areas, semiotic associations were founded many years ago: the International Association for Visual Semiotics/Association Internationale de Sémiotique Visuelle and the International Association for Word and Image Studies, respectively (*see* **Visual Semiotics**).

Film and Television Semiotics

Although sometimes film theorists have their reservations about subsuming film theory under the trendy label of media studies, film has to be considered a part of the media semiotic endeavor. Since the 1960s, a large amount of theoretical reflexion on film is based on film semiotic theories and analyses, and both central theoretical concepts and models of analysis in film and television are of semiotic origin. Accordingly, film semiotics plays an important role within applied semiotics in general.

The film semiotic discourse dates even further back than media semiotics in general, and it unfolds in several phases that are characterized by changing paradigms, thus showing that there is no such thing as a monolithic, unified film semiotics (in the same way as we should speak of 'semiotics' rather in the plural than in the singular). The plurality of film semiotic approaches, concepts, and models mirror the plurality of schools and currents that are today subsumed under the general label 'semiotics.'

At the very beginning, we find the writings of the Russian Formalists (Boris M. Ejchenbaum, Viktor B. Shklovskij, Jurij N. Tynjanov) of the 1920s, who can be considered to be film semioticians *avant la lettre*. Both in individual publications and in the programmatic collection *Poetika kino* (1927), they focused on the question of film as language (discussing a syntax – 'film sentence' – and semantics of film) and on literary, in particular poetic, features of film. The fundamental distinction between *syuzhet* ('plot') and *fabula* ('story') goes back to their writings.

During the following decades, there are a few, by now almost legendary publications, like Jan Marie Lambert Peters' thesis *De taal van den film* (1950).

The first stage of a broader semiotically based reflection on film started almost simultaneously with the first proliferation and organizational establishment of general semiotics in the middle of the 1960s (for instance, the International Association for Semiotic Studies IASS-AIS was founded after several years of preparatory conferences in 1969 in Paris). The major topic discussed in these years was the question whether film can be considered a language (in the sense of *langue* or language system) and, accordingly, be analyzed within the framework of semiolinguistic models (mostly in the Saussurean tradition). The search for the smallest units and a double articulation in the linguistic sense culminated in the well-known discussions between Eco and Pasolini at the 1965 and 1966 Pesaro film festivals. A first answer was given by Christian Metz, who considered cinema as a language without language system (cf. Metz, 1968: 65) and presented a differentiated theory of (general and particular) cinematographic codes and nonspecific codes (Metz, 1971).

A second phase (1970s and early 1980s) is characterized by a stronger orientation towards film reception and the recipients, based on (at least) two different paradigms: psychoanalytic and Marxian models in the tradition of Lacan and Althusser respectively. (With regard to the psychoanalytically inspired film semiotics, one influential publication has to be cited: Metz's *Le signifiant imaginaire* [1975].) In addition, this decade is also the period of the bloom of British film and television studies, which to a great deal focused on the sociocultural positioning of the recipient and the role it plays in her/his reception and constitution of meaning.

Finally, the film semiotic discourse in the 1980s and 1990s, the third phase, is characterized by a real plurality of approaches, concepts, and models and a proliferation of semiotic writings in film and television studies. On the one hand, film semiotic reflections (both theoretical and analytical) entered a positive exchange with several neighboring disciplines and related fields (like feminist theories as well as models rooted in narratology or discourse and text theory). Another strong field, with which general semiotics started to get in contact, is constituted by the cognitive sciences; accordingly, we can speak of the beginnings of a cognitive turn in film semiotics in these years. On the other hand, classic semiotic paradigms were taken up again and developed in new directions, like in neoformalist or semiopragmatic approaches. Part of this trend is also a reconsidering of those concepts and models from general semiotics that have so far not been adapted to film theoretic contexts. One way is to go back to the 'founding fathers,' as for instance Charles S. Peirce, and their writings that were also subject to changed readings and interpretations during the last decades. Since the 1960s, a few (film) theorists (like Peter Wollen [1969] or Gilles Deleuze [1983, 1985]) have dealt with his thought, and some of Peirce's concepts, like the trichotomy of icon–index–symbol belong to the standard terminology in film and media studies. Nevertheless, a close reading of Peirce's works will certainly bring helpful inspirations for film studies. One example of the application of Peircean semiotics to film are the works of Werner Burzlaff who examines montage and stylistic devices on the basis of the Peircean phaneroscopy (cf. 1992). But there are many more semiotic/semiophilosophic texts from the various traditions, schools, and currents that could contribute to a reflection on film. Birgit Recki (2004), for instance, presents Ernst Cassirer outside the philosophical circles to a public

interested in film studies and adopts aspects from his *Philosophie der symbolischen Formen* for her discussion of film as an artistic medium.

Digital Media/Hypertext/Computer/Internet

The most recent fields of research in media semiotics are 'new media' or 'digital media,' hypertextuality, and virtual environs/virtual reality. One of the earliest presence of this field was the 1995 conference (cf. Nöth, (ed.), 1997). Papers in this area are dealing with various topics: the fundamental questions of representation in the digital age; whether the computer can be regarded as a (semiotic) medium (Santaella, 1998; cf. Andersen *et al.*, 1993); the production and reception of hypertexts (Landow, 1994); the (narrative) structure of computer games (Wenz, 1998); or the semiotic analyses of expert systems. However, semioticians in this field are not only occupied with the analysis, but even with the sign-theoretically reflected production of multimedia applications or websites (Stockinger, 1993; Stockinger *et al.*, 1998). Both directions, semiotic theory and semiotically rooted practice, as well as their integration can be found at the annual COSIGN conference on computational semiotics for games and new media.

Topics across the Media

Apart from the fundamental questions of representation and signification with regard to media, or the particularity of the sign systems used for media semioses, there are some specific fields media semiotics has dealt with throughout the decades.

Media texts are increasingly characterized by intertextuality and intermediality, respectively, which are areas of genuinely semiotic research. The scholar most often quoted in connection with 'intertextuality' is Julia Kristeva (1967, 1980), who is credited to have coined the term in her essay "Bakhtine, le mot, le dialogue et le roman." Topics of research closely related to intertextuality are questions of reflexivity and self-awareness of/in media texts. Of particular interest is the ever increasing number of self-reflexive media texts, that is media texts dealing with, and occasionally criticizing, their own medium (institution) and its conditions and modes of production, and sometimes even reflecting on their own status as a medium text. Multimediality, on the other hand, exceeds both the question how individual texts can be related to each other, and how multimodality can be achieved in texts (cf. Hess-Lüttich and Schmauks, 2004).

Another area of semiotic analysis that touches several different media is constituted by the stories, the narrative.

Finally, semiotics is not only concerned with syntactics and semantics, with formal questions, and with the structural properties of media texts. From the very beginning of the semiotic enterprise, there was always a strong focus on the pragmatic dimension of sign processes and their role within a sociocultural context, in short: a sociosemiotic view on the topic. Given the increasing mediatization of our world and the role globalized communication and media (texts) play in our today's societies (in particular their omnipresence and the merging of telecommunication technologies and media), this feature is one that makes semiotics particularly important, also for the future. Pragmatics asks about sign work, about the production and reception (or reproduction) of texts, about the use and misuse of signs and sign systems, about the ideological implications of messages transmitted, and about the way people can be trained to handle these messages in order to resist manipulative tendencies and to learn to cooperate for a better future, as it was foreseen already by Morris (1946), or formulated more recently by Ponzio and Petrilli in their 'semioethics' (2005).

Medical Communication, lingua francas

I Taavitsainen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The term *lingua franca* refers to the earliest Romance-based pidgin and has gained the meaning of a widely used auxiliary language to enable communication between people of different mother tongues. At present, English is the most widely spread *lingua franca* of the western world, used in several fields, including science and medicine.

Latin was the *lingua franca* of Western medical writing for several centuries. The roots of Western medicine lie in Greek; medical learning was transmitted in Latin translations of Greek and Arabic texts, mostly by translators whose first language was not a European vernacular but Arabic or Greek. Galen's texts became available in the 13th century in Latin commentaries, with several layers of additions. Medical texts started to be translated into vernacular languages such as French, English, German, Portuguese, and Catalan in the 14th and 15th centuries, almost simultaneously in different parts of Europe (see, e.g., Crossgrove *et al.*, 1998). Latin retained its firm position as a pan-European language of science. The situation started to change in England at the end of the 17th century, and several authors published in both

Medical Communication, lingua francas

I Taavitsainen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The term *lingua franca* refers to the earliest Romance-based pidgin and has gained the meaning of a widely used auxiliary language to enable communication between people of different mother tongues. At present, English is the most widely spread *lingua franca* of the western world, used in several fields, including science and medicine.

Latin was the *lingua franca* of Western medical writing for several centuries. The roots of Western medicine lie in Greek; medical learning was transmitted in Latin translations of Greek and Arabic texts, mostly by translators whose first language was not a European vernacular but Arabic or Greek. Galen's texts became available in the 13th century in Latin commentaries, with several layers of additions. Medical texts started to be translated into vernacular languages such as French, English, German, Portuguese, and Catalan in the 14th and 15th centuries, almost simultaneously in different parts of Europe (see, e.g., Crossgrove *et al.,* 1998). Latin retained its firm position as a pan-European language of science. The situation started to change in England at the end of the 17th century, and several authors published in both

languages (Webster, 1975: 267). Latin retained its position longer in other parts of Europe, e.g., in German-speaking countries. It is possible that journal publication in medicine from the 17th century onward played a part in nationalizing medical communication.

In the early 20th century, there were rival languages for the *lingua franca* position in science: French, German, and English. German was a very strong candidate before the Second World War. German had served as a *lingua franca* in large parts of Europe for centuries, for example, in the Baltic area since the Middle Ages, and the names of several scholarly journals and series in many fields are still in German. The situation started to change in the 1950s and 1960s in favor of English with the increasing impact of Anglo-American culture. The development has been extremely rapid in the last decade, and English prevails in medical research writing to the extent that researchers have noticed signs of register narrowing; for example, in Scandinavian languages the trend was noticed more than ten years ago (Gunnarsson and Bäcklund, 1995: 47). Practically all medical dissertations in the Nordic countries are written in English, and the same trend has been noticed in other parts of Europe. The widening circles of English in medical research writing can easily be verified by looking at the authors of recent issues of the *British Medical Journal*.

The former *lingua franca* of medicine, Latin, has not entirely lost its position. In hospital communication between medical doctors, Latin is still used in written documents in a highly conventionalized form, for example, in the Nordic countries the diagnoses are regularly given in Latin in the title line, and Latin anatomical terminology is employed. As a rule, the rest of the medical report is in the native language, for example, in Finnish or Swedish. A new feature is the use of English abbreviations and English words like sign, instead of the native word. In pharmacological use and in medical recipes, Latin abbreviations prevail; abbreviations provide an easy way out of the problem with inflectional endings as Latin is no longer taught much in schools. The trend is toward the increasing use of English.

The Information Society and the Changing Status of Experts

Fifty years ago, authorities were generally more clearly defined in society than they are today. Teachers, doctors, and lawyers had undisputed expert status and as such they were highly respected and their authority was rarely questioned by the average citizen. Academic training was the exception rather than the rule and a much larger number of people were employed within the agricultural sector or within other manual sectors following a very limited period of schooling. Being practical, skillful, and able to manage were important values, whereas intellectualism, theoretical discussions, and criticism of society were not the order of the day. To a large degree, knowledge was still passed on from your elders and gained by experience. Although not academically trained, most people (men) were skilled in something often through some form of apprenticeship and areas of expertise were generally acknowledged.

Gradually, this has changed. In the 1960s, academics started challenging the authorities and their status as omniscient. They demanded the right to have a say (not only within their own fields) and this demand required information. From the 1960s on, the number of people receiving academic training

languages (Webster, 1975: 267). Latin retained its position longer in other parts of Europe, e.g., in German-speaking countries. It is possible that journal publication in medicine from the 17th century onward played a part in nationalizing medical communication.

In the early 20th century, there were rival languages for the *lingua franca* position in science: French, German, and English. German was a very strong candidate before the Second World War. The Information Society and the Changing Status of Experts

Fifty years ago, authorities were generally more clearly defined in society than they are today. Teachers, doctors, and lawyers had undisputed expert status and as such they were highly respected and their authority was rarely questioned by the average citizen. Academic training was the exception rather than the rule and a much larger number of people were employed within the agricultural sector or within other manual sectors following a very limited period of schooling. Being practical, skillful, and able to manage were important values, whereas intellectualism, theoretical discussions, and criticism of society were not the order of the day. To a large degree, knowledge was still passed on from your elders and gained by experience. Although not academically trained, most people (men) were skilled in something often through some form of apprenticeship and areas of expertise were generally acknowledged.

Gradually, this has changed. In the 1960s, academics started challenging the authorities and their status as omniscient. They demanded the right to have a say (not only within their own fields) and this demand required information. From the 1960s on, the number of people receiving academic training

has exploded. Jobs that just a few decades ago required very little schooling cannot be had without years at college. Written material is distributed like never before, the various media provide a constant stream of information and the advent of the computer and the Internet in particular has catapulted us into the era of the information society. Many citizens and consumers today consider information their right in a democratic society, but there is also another side to the coin. Apart from the self-assured, critical, and challenging citizen, there are still many people who find it difficult to digest even fairly simple texts and who are not used to asserting themselves publicly. This group of people is at a disadvantage in the self-service information society. Authorities have been able to lower their level of personal service and have become used to handing out brochures and referring people to web pages. Furthermore, within some areas the reason for publishing huge amounts of information is not a true desire to convey information but, rather, a way to limit responsibility. That is why, for example, patient package leaflets contain long lists of extremely unlikely side effects, a measure that prevents the medical company from being taken to court on a 'should-have-told' basis.

The New Roles of Medical Experts

Society is now at a stage at which it is possible to obtain information about almost anything within a very short period of time. This has changed the way in which experts and authorities are perceived. Now that there is easy access to so much information it has become possible, and quite common, to criticize and challenge the views and decisions of experts. Within the field of medicine this has led to new roles for medical professionals and the entire medical industry (it should be noted that the contents of this section first and foremost apply to the industrialized world).

To a large degree, the medical profession is still highly respected and much authority still surrounds the health-care practitioner. Nevertheless, many patients do not accept a diagnosis as readily as they used to, they seek second opinions, read up on the matter themselves, and suggest alternatives, etc. Once they are convinced the diagnosis is right they do not always accept the treatment proposed by the doctor; they may challenge his/her views by means of the latest research available on the Internet and they may seek alternative treatment. Patients want access to their files to check what is going on. The medical industry is being met with claims of openness and information about the medicine they produce. Patients want to know about possible side effects (and to have them graded statistically) in order to decide whether to take the medicine prescribed or not. Medical experts no longer just diagnose and prescribe; they are expected to be willing and able to inform and discuss with the patient to a degree never seen before. Generally speaking, patients are more literate than ever and used to seeking and digesting new information. But even the most well-educated part of populations do, however, not possess the background knowledge of a medical expert and are linguistically speaking not part of the discourse community of medical experts. There is no doubt that patients who are used to digesting complex texts will often benefit from the information they obtain. However, many people do not possess this ability and this is problematic, because in today's society they are expected to. In earlier days, the doctor assumed complete responsibility; on the one hand, this meant that the patient was left to the mercy or competence of the individual doctor; on the other hand, it meant that the patient could leave things in the hands of fate and the doctor and did not have to carry the burden of having to be informed and being able to make informed decisions. But in the 21st century, authorities expect people to understand the technical and semitechnical language of doctors, various health campaigns on prevention and warning signals, the contents of patient package inserts (also in connection with the increasing amount of medicine sold over the counter, i.e., without any consultation), a number of informative brochures on specific ailments, their own medical files, and so on. This may be quite feasible to part of the population, but is likely to be problematic to many people.

What Is Medical Language?

Medical language is traditionally regarded as the language used by medical experts when communicating in an expert-to-expert context. It is the language of the 'specialist,' often defined as a special language as opposed to general language used by the general public in everyday situations:

> Special languages are semi-autonomous, complex semiotic systems based on and derived from general language: their use presupposes special education and is restricted to communication among specialists in the same or closely related fields. Sager *et al.* (1980: 69)

Those who master medical language have been encultured or socialized into the language. The student of medicine automatically becomes a student of medical language when attending university to become a health-care practitioner. Thus, apart from acquiring knowledge about the medical field, s/he

learns to communicate with peers using the linguistic tools appropriate in the medical context. It is a process in which books, medical journals, traineeships at hospitals, conversations with lecturers, fellow-students, doctors, etc. contribute to a gradual buildup of a specialist, medical language. When the student graduates, s/he not only possesses thorough *knowledge* of the medical field, s/he also masters the *language* of the medical discourse community.

Characteristics of Medical Language

The most obvious characteristic of medical language is its extensive use of words related to the subject matter – also referred to as 'medical jargon.' Apart from the medical jargon, medical communicators also favor a passive and impersonal style that focuses on objective, measurable phenomena rather than concrete actions. This style is attained through the use of heavy noun phrases (with nominalized actions), passive clauses, and a preference for third-person pronouns rather than first personal pronouns.

The medical jargon and the passive and impersonal style allow experts to provide precise and condensed information for other experts who are trained to perceive and consequently talk about the physical world in a rational, objective, and measurable way.

An example could be the pharmacist describing the attributes of a medicinal product in the so-called product summary – which is an official document from the pharmaceutical company that provides approving authorities with information about a particular product in order for them to authorize the marketing of the product. It gives health-care practitioners detailed information about a medicinal product as in the following extract:

> The antidepressant, antiobsessive-compulsive and antibulimic actions of fluoxetine are presumed to be linked to its inhibition of CNS neuronal uptake of serotonin. Studies at clinically relevant doses in man have demonstrated that fluoxetine blocks the uptake of serotonin into human platelets. Studies in animals also suggest that fluoxetine is a much more potent uptake inhibitor of serotonin than of norepinephrine. (http://pharma-help.com)

This example is used within a medical discourse community that is 'pure,' in the sense that the community is composed of equals or near-equals in knowledge and professional role (pharmacist to doctor). However, medical genres and medical discourse are not necessarily restricted to that of experts talking to experts. As patients, consumers, and members of society in general, nonspecialists momentarily enter the medical discourse community – not as producers but as *consumers* of medical texts such as patient package inserts for medicinal products, social marketing leaflets explaining the dangers of smoking, or when consulting GPs or pharmacists. Therefore, medical language is not restricted to the discourse community of experts but can also be found in communities in which the addresser is a professional and the addressee is a layperson.

The need for medical information accessible to people outside the professional medical domain has brought about a significant change in the premises of medical communication. The traditional symmetrical communication between equals (e.g., pharmacist to doctor) has been challenged by the demand for *asymmetrical* communication between experts and laypeople (e.g., doctors to consumers). This demand calls for recognition of a medical language at *different levels of abstraction*. If both communicators are specialists, the highest level of abstraction (i.e., 'traditional' medical language) is the obvious choice. If the communication is asymmetrical (professional-lay), the medical subject matter has to be adjusted to the knowledge of laypeople. In practice, this means that texts, which originate from an expert discourse community but serve as the basis for a consumer-oriented version, need to be 'translated' to become meaningful to nonexpert readers.

What Is Professional-Lay Medical Language?

This section deals with written communication though many features apply to oral communication as well.

Target Group

In 1859, Kierkegaard wrote about the following situations in which experts, or people who know more than others, want to convey their knowledge to other people:

> If I am to succeed in guiding another human being towards a certain goal, I have to find the place where he is and start right there [...]. In order to help somebody, I certainly have to understand more than he does, but first and foremost understand what he understands. (our translation of Kierkegaard, 1869, in Becker Jensen, 2001: 18)

Kierkegaard tells us that if you do not have this understanding it is no help that you are more knowledgeable than your target group, and he adds that:

> All true helpfulness begins with humbleness towards the person I seek to help, and this is why I have to understand that helping is not wanting to rule, but to serve. If I cannot do this, I cannot help anybody (our translation of Kierkegaard, 1869, in Becker Jensen, 2001: 18).

Kierkegaard points out two important maxims that are still valid for expert-to-layman communication: It is the level of the target group which should determine the level and style of the text, not the writer's level – otherwise the extra knowledge of the expert becomes useless to the reader. The writer must be humble and possessed of a true desire to be of assistance, i.e., should not be preoccupied with his own status and authority.

The target group in expert-to-layperson communication is often potentially the entire population and must therefore be characterized as very broad indeed, which is why the visualization of a target group may well be a very substantial problem to the writer. The expert writer is in danger of overestimating his audience because of his own extensive knowledge and may be afraid of sounding patronizing if too much is explained. An expert writer may also feel that very simple language questions his status as expert – after all, expert language signifies expertise and authority to many. All things considered, if there is a true desire to make a text understandable to all laypeople and not just half of them the safe way is to use the lowest common denominator as a yardstick. If there is a well-defined target group, the lowest common denominator within that group should be used.

Kierkegaard's two maxims should be kept in mind at an overall level, whereas the following may be of assistance at a more specific level when writing for laypeople.

Characteristics of Professional-Lay Medical Language

Incomprehensible Medical Jargon Perhaps the most defining feature of medical – or expert – language is the use of expert terms unknown to most people. For example, we may see the use of 'therapeutic indications,' 'contra-indications,' and 'interactions' in the headlines of an insert. These terms should be replaced by lay terms when possible or should be paraphrased. It should be noted that most medical jargon has Latin or Greek roots, but that the extent to which Latin medical terms have been incorporated in everyday language varies greatly from country to country. French and English have, for instance, been more receptive to Latin than German and Scandinavian languages.

False Friends False friends within an expert-to-lay context are words and expressions that are used both in everyday situations and in special contexts but in which the meaning of the words differs depending on the context in which the words are used. For example, the expression 'to administer' is the formal use of giving someone a drug. However, the expression is also used in a more informal sense in business or legal settings but with a totally different meaning. It may be very confusing to the reader if he knows the word well from other contexts but cannot make sense of it in the context in question. The use of such terms should therefore be avoided.

Inconsistent Use of Synonyms Generally, medical language is characterized by sparse use of synonyms but, when they occur, perhaps especially in expert-to-lay texts in which semiexpert terms or lay terms are used, too, the reader who does not possess the expert knowledge needed to judge whether the terms are synonyms or not may become confused when confronted with two or three different terms for the same thing. This is, for example, the case when 'lactation' and 'breastfeeding' are used interchangeably. Stylistic variation should be avoided if there is a risk of sacrificing understanding.

Long or Complicated Words or Expressions Traditionally medical expert language often makes use of officialese. Strictly speaking, this has nothing to do with medical jargon or with the advantages of expert language such as brevity and precision, rather the opposite. Still medical texts are often characterized by unnecessarily long or complicated words and expressions which make the text more difficult to digest. These superfluous words or blown up expressions should be removed and replaced with more simple ones.

Long and Complicated Sentences These are often a direct consequence of situations in which long and complicated words and expressions coupled with a too complex sentence structure result in lengthy, inflated sentences. Such sentences should be reduced by omitting superfluous words and expressions and can in many cases be split up into two or three shorter sentences.

Passive and Impersonal Style In expert communication, it is often not particularly relevant to know who the 'actor' is. Thus, instead of using the active voice, medical experts rely on a passive style making use of the passive voice and nominalization. In the passive voice, the person performing the action is deleted. This strategy may be quite useful in texts in which the actor is either unknown or simply not important, but in cases in which the patient needs to know that *s/he* is to perform some kind of action (e.g., in connection with a patient package leaflet) it is important to use the active style. The passive style makes the text impersonal and it forces the reader to take extra

mental steps as s/he converts the passive sentence into an active one in order to work out "who is doing what." For example, an impersonal expression such as "X should not be taken during the first 3 months of pregnancy" should be replaced by a more active expression "you should not take X during the first 3 months of pregnancy." Passive sentences should be turned into active voice and undue nominalizations should be avoided in favor of the more direct verbal form.

Too Much Information in One Sentence Contrary to sentences containing superfluous words, these sentences are complex because they contain too much *relevant* information. For example, "This includes previously untreated patients and patients who have previously responded to treatment with X, but whose condition has recurred." Apart from listing too much relevant information, the sentence is also complex because it is packed with heavy noun phrases. Very often, sentences become rather long and complex because the writer adds extra information to the noun by means of pre- and postmodifiers. The result is heavy noun phrases, which – when unpacked – would constitute sentences in their own right. To nonexperts, these sentences can be very difficult to unpack correctly. Such sentences should be edited by splitting them up into two or three shorter sentences.

Remnants from Translation Many medical experts are used to reading and discussing in English although it is not their native language. Modern non-English medical language is often very influenced by English lexis and even syntax. This may be a problem to non-English speaking laypeople.

Presuppositions A text that to an expert has a logical structure may not be logical to a layperson. If the writer relies on presumed (but nonexisting) background knowledge of the reader, the reader may be unable to follow the thoughts of the writer and may think that he jumps to conclusions.

Evidently, it is not realistic to completely avoid all of the above expert features. But the reason why expert language may be difficult to laypeople is the fact that these features tend to appear together in a sentence. Several studies show that they make the text less accessible to the general reader (see, e.g., Killingsworth and Gilbertson, 1992; Killingsworth and Steffens, 1989).

Length There are of course different conventions for the length of a text, but lay texts should never be longer than strictly necessary.

Print Size Information on medicine is often provided in far too small print that may discourage readers even before they have started. The print size should be reader-friendly.

Order of Information The order of information should be as logical as possible. Usually a sound strategy is to place the most important information in the beginning of the text.

Headings Well-placed, informative, and precise headings help weak readers navigate through a text. Headings should be written in clear and understandable terms and should not be too long.

Pictograms For instructional texts, pictograms may be a good solution, but the pictures or symbols should in no way be open to interpretation. This is more difficult than it sounds – a picture of a glass of water may to one reader mean that a pill should be dissolved in a glass of water, whereas to another it indicates that a glass of water should be drunk after swallowing the pill.

Conclusion

In spite of this attempt to describe the 'ideal' characteristics of professional-lay medical communication, professional-lay communication is still in its infancy and the discourse conventions are not in place. Professional-lay discourse in the medical context may best be described as a 'pseudo' discourse for the time being, in which professionals – with varying success – try to adapt their medical language to a mixed audience (potentially the entire population) whose knowledge of the subject matter and the discourse conventions of the medical field is very restricted. What we experience is a semiprofessional discourse that attempts to merge the qualities of traditional medical language with the discourse conventions of 'plain English' style guides. One could speculate about the reasons for the lack of successful professional-lay communication. No doubt many of the problems can be attributed to the enculturation of health-care practitioners into the medical domain through language that means that the *discourse* and *practice* of medicine are difficult to separate. More specifically, it has the following consequences:

- Medical experts generally lack the ability to downgrade their special language in order to accommodate a target group of nonexperts. The medical experts are experts within medicine, not within plain English communication.

- Medical experts feel less inclined to adopt a fully professional-lay discourse, as it may question their status as experts – after all, expert language signifies expertise and authority to many. They may even feel that talking medicine at a lower level of abstraction demystifies their profession and results in status loss.
- Finally, medical experts resist the professional-lay discourse for ideological reasons. Because of their scientific schooling, medical experts may regard professional-lay discourse a language for *mediation*, inappropriate for talking about medicine because the required simplification in professional-lay discourse (which promotes a personal, subjective, action-oriented style) does not meet the demands for precision, conciseness, objectification, and passivity, which is the paradigm of medical science.

Thus, instead of developing a professional-lay medical discourse, which enables experts to explain medical concepts at a lower level of abstraction, the experts resort to their habitual way of communicating (i.e., the language into which they have been socialized when acquiring their expert knowledge) in spite of the fact that their expert language is difficult to understand for 'outsiders' and therefore hampers the readability and usability of consumer-oriented medical documents.

And so, today, we face a situation in which, in spite of the fact that the medical community produces numerous documents for patients (package inserts, health leaflets, information letters prior to hospitalization, etc.), the professional-lay discourse has not been fully developed (and embraced) by the medical discourse community. Therefore, the discourse remains a hybrid between traditional medical language and consumer-oriented plain English.

The Scientific Medical Discourse Community

The construction of knowledge is both an individual and a social task. It is a continuous dialectical process that has been taking place for generations. This process has adopted different forms of communication, namely, oral (conferences, conversations, dialogues, remarks, among other spoken genres) and written (editorials, research articles, letters, peer reviews and referees' remarks, case studies, and even chats and e-mails).

New knowledge is drawn from the conversion of research resources derived from "how authors, editors, and reviewers together transform the raw material of manuscripts into the finished product of validated knowledge claims" (Chubin and Hackett, 1990: 95). This is usually carried out through a series of conventions that each discourse community has. While attributing to the communicative purpose the role of linking genres, tasks, and discourse community goals,

- Medical experts feel less inclined to adopt a fully professional-lay discourse, as it may question their status as experts – after all, expert language signifies expertise and authority to many. They may even feel that talking medicine at a lower level of abstraction demystifies their profession and results in status loss.
- Finally, medical experts resist the professional-lay discourse for ideological reasons. Because of their scientific schooling, medical experts may regard professional-lay discourse a language for *mediation*, inappropriate for talking about medicine because the required simplification in professional-lay discourse (which promotes a personal, subjective, action-oriented style) does not meet the demands for precision, conciseness, objectification, and passivity, which is the paradigm of medical science.

Thus, instead of developing a professional-lay medical discourse, which enables experts to explain medical concepts at a lower level of abstraction, the experts resort to their habitual way of communicating (i.e., the language into which they have been socialized when acquiring their expert knowledge) in spite of the fact that their expert language is difficult to understand for 'outsiders' and therefore hampers the readability and usability of consumer-oriented medical documents.

And so, today, we face a situation in which, in spite of the fact that the medical community produces numerous documents for patients (package inserts, health leaflets, information letters prior to hospitalization, etc.), the professional-lay discourse has not been fully developed (and embraced) by the medical discourse community. Therefore, the discourse remains a hybrid between traditional medical language and consumer-oriented plain English.

Medical Discourse and Academic Genres

The Scientific Medical Discourse Community

The construction of knowledge is both an individual and a social task. It is a continuous dialectical process that has been taking place for generations. This process has adopted different forms of communication, namely, oral (conferences, conversations, dialogues, remarks, among other spoken genres) and written (editorials, research articles, letters, peer reviews and referees' remarks, case studies, and even chats and e-mails).

New knowledge is drawn from the conversion of research resources derived from "how authors, editors, and reviewers together transform the raw material of manuscripts into the finished product of validated knowledge claims" (Chubin and Hackett, 1990: 95). This is usually carried out through a series of conventions that each discourse community has. While attributing to the communicative purpose the role of linking genres, tasks, and discourse community goals,

Swales (1990: 34) brought up a conceptualization of discourse communities:

> Discourse communities are socio-rhetorical networks that form in order to work toward sets of common goals. One of the characteristics that established members of these discourse communities possess is familiarity with the particular genres that are used in the communicative furtherance of those sets of goals.

This is why he further adds that genres do not belong to individuals, but "are the properties of discourse communities."

Dialogical communication among scientists within a discourse community takes different shapes and forms. More often than not, their communication is an effort to win acceptance by their readership, particularly when controversial research is involved. In Myers's (1990: 144) words, scientific texts often represent "a negotiation of knowledge claims, not simply the communication of knowledge." This negotiation is carried out through the different genres at the disposal of a given discourse community. In addition, genres not only are established sites of social action, but also contribute to coordinate the work of groups and organizations. This social action in the science-making process is carried out through the scientific communication in a continuous exchange of information with other researchers in the same field and finally represents the acceptance of the investigation by the scientific community.

Communication among scientists and between scientists and their readership has been particularly enhanced by developments in computer science through which a web of information is distributed with no limitations in sight. "Links from electronic articles," wrote Delamothe (2002: 1477), "can pass backwards, forwards, and sideways to other articles." Delamothe further added, quoting from the *Charleston Report* (2002, 7, 1–2), that "a single document is no longer the pivot of knowledge but rather a node in a cognitive web in a system of coupled databases." The Internet potential is said to be unlimited, at least in reference to most first-world countries. Unfortunately, however, this does not hold true for third-world countries. Data show that only 2% of the world population has access to the Internet.

Written Communication

Since the 17th century, medical writing has gone through what Lang (2000) called the age of "formalized medical writing," in which a series of major steps took place: the first Western scientific journal, *Journal des Scavans*, was published in French and in English by Denis de Sallo, a member of the French *Parlement*, in 1665, antedating the *Philosophical Transactions of the Royal Society of London* by only 10 weeks. The first English medical periodical was the *Medicina Curiosa*, of which the only two issues extant appeared on June 17, 1684 and October 23, 1684. Over a century later, in 1797, the first medical journal, *The Medical Repository*, was founded in the United States. In 1812, J. C. Warren established *The New England Journal of Medicine and Surgery and the Collaterial Branches of Science*. This journal, after merging with *Medical Intelligencer*, became the weekly *Boston Medical and Surgical Journal*, which has been the official conduit of information of the American Medical Society since 1914, and, finally, in 1928 it became *The New England Journal of Medicine*. In Great Britain, the first issue of the *Provincial Medical and Surgical Journal*, considered the precursor of the *British Medical Journal* (*BMJ*), was published in 1840. A hundred year later, the American Medical Writers Association (AMWA) was established. In the 1960s, authors began to incorporate abstracts in medical journal articles and also the first edition of the *AMA Manual of Style* appeared. Pasteur introduced the methods section in the 1870s, essentially creating the IMRD (Introduction, Methods, Results, Discussion) format, also known as IMRAD (Introduction, Materials and Methods, Results And Discussion) and including TAIMRAD (Title, Abstract, Introduction, Materials and Methods, Results, And Discussion) (Maher, 1992); however, it was not until 1972 that this structure became the official standard for presenting scientific information (Standard Z39 of the American National Standards Institute). In 1979, the Uniform Requirements for Manuscripts Submitted to Biomedical Journals were published, and the structured abstract was introduced in 1987. Finally, in 1997, the Consolidated Standards for Reporting Trials Statement (the CONSORT Statement) was published.

The organization of top biomedical journals is not always well delimited and structured, resulting in dissimilar patterns. This can be attested by looking at five of the journals most widely consulted by researchers, namely, *Annals of Internal Medicine* (twice monthly), *British Medical Journal (BMJ)* (weekly), *Journal of the American Medical Association (JAMA)* (weekly), *The New England Journal of Medicine* (weekly), and *The Lancet* (weekly), all listed in *Index Medicus* and Medline. For example, most of them will include the typical original and revision articles, editorials, reports from clinical medicine, occasional notes or brief notes, book and journal reviews, and the like. In addition, some will feature special articles, such as *The New England Journal of Medicine*, in which a series of cases from the registry of the Massachusetts General Hospital is presented. Both *The Lancet* and *Annals of Internal Medicine* also offer short comments and brief communications, and the *BMJ* has

special cases based on Internet reader feedback. Of the five top medical journals mentioned, *BMJ* and *The Lancet* offer free access to their full contents, although the latter requires the user's free registration; quite a few articles are also offered in *JAMA*. Only contents (major features) and abstracts can be freely accessed in the rest of journals and sometimes a summary for patients (as in *Annals of Internal Medicine*) can be accessed. Obviously, the easier the access to these journals, the more feedback is obtained from the readership through the Internet, which makes the process one of the most innovative means of communication to and from a given medical journal.

Academic Genres in Medicine

The Importance of Worldwide Communication in the Medical Profession

Communication in medical English has been essential throughout the history of medicine (*see* **Medical Discourse: Sociohistorical Construction**). As medical science became internationally widespread, the need to keep in touch for the sake of the development of the science has become increasingly important for a number of reasons: first, as a means to complement research findings; second, to avoid the repetition of the experiments that yielded no positive results; and third, to control new diseases. These three factors are closely interconnected as the following examples illustrate: when AIDS began to spread around the world, major medical research centers had to share information, first, in order to control the disease, and, second, to create useful treatments that, frequently, were the results of complementing reports of previous investigations by other colleagues. Most likely, the SARS syndrome will again show the relevance of all these factors.

The words that doctors articulate in medical communication may be organized into various formats, but they always follow well-designed communicative written or spoken patterns. Linguists have come to label these recognizable patterns as 'academic genres' (Swales, 1990). The fact that medical professionals systematically resort to specific genres is a key factor in medical communication. A second essential element is the fact that doctors around the world basically communicate in a single language: English. This presents a series of consequences for all professionals in the field: in the first place, a reasonable level of English proficiency must be attained by doctors in order to read about new advancements in their discipline if they are to internationally publish their findings (necessary for promotional purposes in most countries). The problem is that the international use of the English language in the medical profession does not simply entail transferring one's findings into English, but also includes proceeding to adapt one's rhetoric to the features that are representative of academic English rhetoric (in its written or spoken versions).

Written and Spoken Genres

The concept of genre, as we have already mentioned, is a key term in medical communication. In fact, all medical communicative events may be classified into specific written or spoken genres (*see* **Medical Discourse: Doctor–Patient Communication**; **Medical English: Conferencing**; **Psychotherapy and Counselling**). With regard to written genres, we may highlight the following: editorials, research articles, abstracts, case reports, review articles, peer reviews, replies to these reviews, letters of acceptance/rejection of a paper, conference programs, medical popularizations, letters of application, book reviews, and letters to the editor (*see* **Medical Journals: Letters to the Editor**), to name but a few. Most of these genres are found in many other academic disciplines; however, each of them develops a set of peculiarities characteristic of the medical profession alone. The general patterns as well as some of the specific medical intricacies of several of these genres are elucidated below.

Stability through Time

Medical genres, especially written genres, have become quite stable in their form, structure, and style. This is mainly due to the fact that, as an independent scientific discipline, medicine is centuries old. This indicates that doctors have had hundreds of years to find fixed patterns – at least in certain paradigmatic genres – that adequately account for their medical findings. The Royal Society of London contributed to the development of key genres such as the research article in medicine. Nowadays, research articles in this discipline tend to follow the well-known IMRAD pattern, which has then been adopted by several other scientific disciplines. Engineering, however, and, in particular, new branches in this area, such as computer engineering, do not necessarily follow the IMRAD models.

Dynamism

The concept of genre, as defined by Swales (1990), implies that these textual patterns are subject to change and evolution. As outlined above, in medical writing there is an overall tendency toward a specific set of fairly stable patterns or genres. This, however, does not mean that the dynamic characteristic of genres is absent in medicine. Medical genres are also sensitive to changes in the outer and wider contexts surrounding the discipline. For instance, the introduction of new

technologies or, as they are currently referred to, the information and communication technologies (ICTs), have triggered a significant amount of change and transformation in the way that research is generally carried out or communicated throughout the world. The ICTs have generated the following major changes in medical communication and in medical genres:

1. The introduction of completely new generic forms (e.g., videoconferences used for lecturing via the Internet or even to carry out surgery under the supervision of a highly qualified surgeon miles away from the operating room; the use of e-mail and websites).
2. The increasing relevance of some already existing specific genres, namely, abstracts, which were used for decades before the invention of the Internet and Computer-Mediated Communication (CMC), even before computer databases. However, the Internet and, most particularly, the World Wide Web have increased the importance of abstracts exponentially as a key means of gaining access to relevant information.
3. The progressive transformation of existing genres, as in the case of conventional research articles that have seen two stages in their inclusion in the web system. Initially, academic papers were simply copies on the Internet that could be consulted or downloaded as they appeared in academic journals; however, the existence of on-line journals and the introduction of faster Internet facilities currently allow medical researchers to incorporate into their papers high-quality images, diagrams with movement, URLs with complementary information, etc. Thus, research articles are now being contemplated with a new set of elements heretofore not included in conventional written academic research articles.

Abstracts

The myriad of medical research papers published around the world today has made abstracts a tool of increasing relevance for medical professionals (*see* **Medical Discourse: Structured Abstracts**). The abstract allows a doctor or a scientist to select papers that are relevant to their everyday practice or research projects. The Internet, on-line databases, and other electronic resources have been added to the already vast research documentation available in conventional academic journals. Not only has the Web assisted researchers in locating relevant papers more quickly but, at the same time, it has also exponentially increased the number of likely to be profitable texts for readings. The medical professional, therefore, will inevitably have to read abstracts in order to be selective when choosing from such a wide array of reading material.

Consequently, the abstract has become an essential genre in medicine. However, important as abstracts are nowadays for medical advancement, it is interesting to note that they are a recent addition to the already established genres, in particular, the research and review papers, to which they are closely related. According to the Ad Hoc Working Group for Critical Appraisal of the Medical Literature (1987: 600), up until the late 1960s, abstracts were not included by most clinical journals. The next step taken by some journals was to move the summary and conclusions to the beginning of the research article, as occurred in *JAMA* and the *Canadian Medical Association Journal*, and shortly thereafter in the *BMJ*.

Editorials

Editorials are introductory articles in the initial pages of an academic journal. As opposed to research articles or case reports, editorials are subjective in their content, they are usually written by a single author, and they reflect the expertise of that person. For instance, Salager-Meyer and Alcaraz-Ariza (2003), when studying the frequency of academic criticism in four written genres of medical discourse, namely, editorials, review articles, research papers, and case reports, found that the frequency of critical statements was significantly greater in editorials than in the other three genres. We believe that the results of this study, although carried out on a corpus of Spanish medical texts in relation to the use of criticism, could also be extended to medical discourse at large. Thus, editorials are subjective, argumentative, and evaluative (in fact, it is their main communicative function). Editorials are written by expert knowledge-holders and knowledge-builders and include more critical statements than other medical genres. It is likely that only peer reviews and book reviews might incorporate a similar or greater level of direct academic criticism, though occurring to a lesser extent.

Editorials are also persuasive in their nature, since they try to convince their readership of the writer's point of view regarding their assessment of the papers being introduced or the ideas being expressed. Accordingly, editorials could be more specifically defined as introductory, persuasive, critical, and evaluative academic texts. They are opinion pieces within medical journals, analyses to evaluate previous and present work, and essays to suggest further areas of research.

Research Articles: Internal Structuring

The scientific or research article can be defined as a technical document that describes a significant experimental, theoretical, or observational extension of current knowledge or advances in the practical application of known principles. The reported findings must not only be original, that is, previously unpublished, but also valid in terms of providing sufficient and important information, and they must be published in accordance with a structure and style previously agreed on by the scientific medical community.

The Internet has introduced a whole new set of parameters in biomedical publication. Top journals in medicine have decided to go on-line with their publications, and this is the case, for instance, for the five top journals mentioned above, to name but a few. In some cases, and for some specific types of articles, journals have begun to avoid printing and, consequently, the articles in question never appear in the print journal. Newmark and Tracz (1997) predicted that, within 5 years, on-line publications would still closely resemble papers.

We believe, with Edward Huth (2000: 5), Editor Emeritus of *Annals of Internal Medicine*, that it may basically be an economic question, a question of "needs and costs in a marketplace." Electronic publishing of journals will actually supersede paper publishing, he adds, "when the new methods satisfy needs of authors and readers better than the paper medium and at a lower price." In addition, through multiple links, information about other articles from different journals is provided, a given paper or a report is cited, and readers are also invited to search for possible related articles through databases such as Medline.

As indicated above, medical papers are basically organized following the IMRAD macrostructure. This is the required macrostructure for both paper journals and on-line publications. Their mode of referencing, through the so-called Vancouver system, has been consistent since it was agreed on at a meeting of medical journal editors in Vancouver, Canada, held in 1978. Let us now examine the internal structure of each section of the IMRAD macrostructure.

Introduction

The introduction is probably the most complex section of the medical research article, but it also follows a more fixed structure than the other three sections do. It cannot be reduced to a mere expression of the author's aim in writing the paper. Rather, it should constitute the connecting link between readers and the research carried out by the authors. Through this fixed structure of the introduction, authors control their ideas and adapt them to their rhetorical aims and to the needs derived from their belonging to a specific scientific community.

The structure of the introduction is constituted by a set pattern based on three basic moves that Swales (1990) described in terms of the CARS model (Create A Research Space), later reinterpreted and applied to the whole body of the medical research article by Nwogu (1997). These three introductory moves and their 'constituent elements' are depicted in Table 1.

Materials and Methods

The methods section, or materials and methods section depending on the type of study (e.g., laboratory-based studies), basically describes the sample and its size, the subjects and criteria for inclusion or exclusion from the research, and the procedures followed in carrying it out. This section includes all the necessary details that enable readers to accurately grasp the research process, to the extent that the scientific community will be able to replicate it with the information provided. Structurally this section may include three basic moves (see Table 2): the first describes the data collection procedure (source and size of data, sample description, and selection criteria), the second describes the experimental procedure (apparatus description and experimental process), and the

Table 1 Introduction moves in the medical research article (Nwogu, 1997: 135)

Move 1:	Presenting background information:
by	(1) Reference to established knowledge in the field
	(2) Reference to main research problems
Move 2:	Reviewing related research:
by	(1) Reference to previous research
	(2) Reference to limitations of previous research
Move 3:	Presenting new research:
by	(1) Reference to research purpose
	(2) Reference to main research procedure

Table 2 Structure of the Materials and Methods section (Nwogu, 1997: 135)

Move 4:	Describing data collection procedure:
by	(1) Indicating source of data
	(2) Indicating data size
	(3) Indicating criteria for data collection
Move 5:	Describing experimental procedures:
by	(1) Identification of main research apparatus
	(2) Recounting experimental process
	(3) Indicating criteria for success
Move 6:	Describing data analysis procedures:
by	(1) Defining terminologies
	(2) Indicating process of data classification
	(3) Identifying analytical instrument/procedure
	(4) Indicating modification to instrument/procedure

Table 3 Structure of the Results section (Nwogu, 1997: 135)

Move 7:	Indicating consistent observation:
by	(1) Highlighting overall observation
	(2) Indicating specific observations
	(3) Accounting for observations made
Move 8:	Indicating nonconsistent observations

Table 4 Structure of the Discussion section (Nwogu, 1997: 135)

Move 9:	Highlighting overall research outcome
Move 10:	Explaining specific research outcomes:
by	(1) Stating a specific outcome
	(2) Interpreting the outcome
	(3) Indicating significance of the outcome
	(4) Contrasting present and previous outcomes
	(5) Indicating limitations of outcomes
Move 11:	Stating research conclusions:
by	(1) Indicating research implications
	(2) Promoting further research

third describes the data analysis procedure (definition of terminology, classification of data, analysis or modification of the instrument or the procedure, etc.).

Results

In the results section, which is the core of the research paper, the results are presented along with charts, graphs, tables, and figures, and the most important findings are underscored. Generalizations (see Table 3) are made based on the results obtained in the study and possible reasons are drawn to justify those results in view of results from other studies, termed by Nwogu (1997) as an indication of "consistent observations." It also provides possible negative results, that is, "those results which do not conform with expected outcomes in the study," so-called "nonconsistent observations" (Nwogu, 1997: 131).

Discussion

The final section, or discussion, has as its main objective the description of how these results fit in with what is already known about the topic of the study. Authors will refer back to the main purpose or hypothesis advanced in the introduction and see whether, in view of the results obtained, it can be held or not and whether it agrees with the findings of other researchers (see Table 4). This section often ends by making a generalization of the results obtained, their implications, and their possible applications, and, if an interesting but as yet unanswered question has arisen from the study, future research is usually recommended. Explanations or speculations may also be necessary to justify the possible limitations of these results.

Table 5 Structure of the RA Discussion section (Reprint from Docherty and Smith, 1999: 1224)

- Statement of principal findings
- Strengths and weaknesses of the study
- Strengths and weaknesses in relation to other studies, discussing particularly any differences in results
- Meaning of the study: possible mechanisms and implications for clinicians or policy makers
- Unanswered questions and future research

Docherty and Smith (1999) argued for a discussion section in which similar points are raised, but with particular emphasis on differences with previous research, as well as on unanswered questions throughout the author's research. They proposed the structure shown in Table 5.

This idea of speculating about the results in the discussion section of the research paper has given rise to a certain amount of polemic. To some extent, it reflects the opinion of those authors who defend a less rigid structure and favor the message itself. However, even though there is widespread acceptance of the writing conventions of a scientific community, some authors prefer – perhaps in an effort to increase their chances of publication in top medical journals – to focus more exclusively on the message itself. It is further contended that there is a tendency among authors to use excessive 'rhetoric' to speculate on the results, going in fact 'beyond data' and thus inducing polemic within the scientific community. Their advice to authors is that they should adhere more to the facts and dwell less on rhetorical devices. Skelton and Edwards (2000), however, are opposed to this restrictive view and suggested that speculation not only is desirable but, in fact, cannot be removed by imposing structural rules in medical research papers, since science is actually speculation, because there is a great deal of doubt and uncertainty. From a linguistic point of view, this is shown by the systematic use of modality in this section. These authors justified their opinion by pointing to the fact that it is in the results section where we find the data and where the statistical conventions are found to determine what is 'significant,' whereas determining how they are 'relevant' is the prerogative of the discussion section.

Case Reports

Case reports constitute a special section within certain journals; in these reports, the medical history of a single patient, usually related to an unusual pathology, is described. However, it is also true that these reports often constitute a case series about a specific and rare disease in which the medical

Table 6 Typical structure of a case report

(a) Presentation of signs and symptoms of the case in question
(b) Description of tests performed and interventions
(c) Presentation of possible diagnoses
(d) Treatment administered
(e) Outcome evaluation

histories of a number of patients may be studied and described. The aim of this type of text is basically to illustrate an aspect of the treatment prescribed and the reaction to that treatment in relation to the disease common to all the patients in the survey or in the series of case reports. Some authors (Iles, 1998) stress the importance of case reports and encourage writing them since it is one of the best ways to get started in medical writing. It has also been the source material in educational programs throughout the medical university curricula.

The structure of this genre depends on the type of case study. In some journals, they appear as a text of considerable length, in which the case report is preceded by an introduction and followed by a discussion. However, the medical literature essentially provides its information based on the structure shown in Table 6.

Iles (1998) proposed a similar structure that consists of the following sections: an introduction, and a case description, followed by a discussion and comments. This structure closely resembles the widely used problem–solution paradigm for text structure that consists of four moves, namely, situation, problem, solution, and evaluation.

The overall frequency of the case report was reduced between 1965 and 1995. This reflects the marginalization of the genre in the medical literature. The total number of case reports in the *BMJ* has gradually decreased: the January 1965 issues contained 43 case reports, between 1970 and 1990, the figures ranged between 8 and 20, and in the January 1995 issues there was only 1 case report. At the same time, the genre has been adapted to new specialized functions. The *BMJ* has introduced special sections in which case reports are selected for specific purposes under the heading 'Lesson of the week' and 'Drug points,' where the didactic purpose is emphasized and the focus is on a particular aspect, such as medication or complications. Another explanation for the decrease of case reports in printed journals is that they are being published in on-line versions.

The following is a paradigmatic example of how a case report can be used with the active participation of readers through the Internet. The *BMJ* presents a case report that involves many interested people and, at the same time, contributes to the science-making process through the subsequent dialogical communication that is produced. This journal includes interactive case reports, under the general heading of 'Clinical Review.' Sodeck *et al.* (2003) presented a three-part case report in three different issues (April 26, 2003; May 3, 2003; and May 24, 2003), in which the case was studied and a follow-up of its progression proposed. Its pedagogical implications become obvious when in the process the readers were asked several questions, thus inviting them to respond through the Internet. The questions from the first two parts produced 127 responses from readers in over 35 different countries, between April 26, 2003 and May 17, 2003. Part 3 offered an added element to this interactive case report; Peile (2003: 1136) postulated that there is more to be learned from the discussion than from the diagnosis and this occurs by focusing primarily on learning.

Review Articles

When speaking of primary and secondary research sources, review articles are considered as examples of secondary research material. They are, nonetheless, a very useful tool for researchers since they give a general view of the topic under discussion. They provide not only possible source materials, but also information on how to locate them. The starting point of review articles is the original medical literature which has already been published. Through a thorough analysis, review article authors give an overview of recent publications and developments in a given area, subarea, or very specific topic. Review articles may then be considered a state-of-the-art description and revision of a given topic.

The literature classifies review articles in three different categories:

Systematic Reviews

A systematic review can be defined as a method of locating, evaluating, and synthesizing evidence. It is subject to predefined criteria for authors, and it has been recently qualified as a "new PubMed filter" (Nahim, 2002). The criteria are usually defined by the journal itself and authors must adhere to them for publication in that given journal. They are usually covered by the set of journal instructions that are mainly referred to as identification, selection, limitation, and interpretation of the bibliographical material. In other words, they have to do with data source, for instance, conference proceedings only; data collection and analysis, in which the process of abstraction of data is described; and the method of analysis and number of variables analyzed in order to obtain the results for the review.

Nonsystematic Reviews

Nonsystematic reviews, also called narrative reviews, are not subjected to any set of pre-established criteria of selection of the materials to be reviewed. Without a rigorous criterion of analysis, however, the authors' opinion is paramount and the risk of bias in the selection of materials, as well as in the identification process, may be present. This creates the risk of producing undesired results, due mainly to the writer's possible bias in reviewing other people's work.

Meta-analytic Reviews

In meta-analytic reviews, a clear set of guidelines for reviewing results of previous studies is offered. Some authors have referred to this type of review as a series of 'analyses of analyses,' in which the review article analyzes data collected from different studies that are considered as being part of one large investigation. Its scope, therefore, is also on one topic but only in terms of analyzing the results obtained in those various studies reviewed. It is not just a simple description of results; it tries to answer the question of why some organ or some mechanism works the way it does.

Peer Reviews

Peer reviews have existed since the 17th century; however, because of their heretofore undisclosed significance, they have been an undervalued genre. For centuries, peer reviews have remained anonymous, their identity accessible only to a select group within the scientific community. This, however, is no longer the case, especially in medicine.

Peer reviews have become absolutely essential in the development of medical research. It is through these texts that decisions on what is to be published or rejected are made (*see* **Medical Writing, Revising and Editing**). High-ranking medical journals have a rejection rate of 80% and elite journals of approximately 90%. Peer reviews are the tool used for these rejections. Nevertheless, authors consider one-third of these reviews as irrelevant and 17.5% as incompetent (see *JAMA*, 1998). If this were true, relevant research is not being published for subjective reasons. *Nature* showed good sense in admitting that its peer review process has not always successfully identified significant new work, but it is not the only journal to have made 'historical misjudgments.' Campanario (2004) compiled an extensive list of rejections and criticisms of manuscripts reporting Nobel-quality breakthroughs.

Peer reviews are expected to be blunt. This is striking in the scientific community, where mitigated assertions and modalized statements characterize the rest of the genres, particularly research articles. In a peer review, on the other hand, one reads an average of only 1.51 mitigated criticisms but 6.88 blunt criticisms. This could explain why 15% of authors qualify the peer reviews they receive as 'impolite,' 73.8% as 'more or less polite,' and only 11.2% as 'very polite' (Kourilová, 1996: 9, 11).

Editors usually rely on reviewers and their comments. Most editors accept or reject a paper on the basis of peer reviews, although this is not always the case. The *BMJ*, for instance, receives over 4000 research papers per year. Approximately two-thirds of these submissions are rejected in-house by editors without consulting external peer reviewers (Schroter and Barratt, 2004). Reviewers have no specific training to carry out their task. They are given instructions only regarding what to assess. Since training programs for reviewing have yet to be implemented, the best solution thus far seems to be to select the best reviewers possible. In this respect, the best quality reviews are generally submitted by younger reviewers (in their 40s rather than in their 60s), who are likely to have a junior status in academia. To be more precise, the ideal reviewer is young, is a resident of the United States, has training in epidemiology or statistics, is a current research investigator, and takes approximately 3 h to write the report (Black *et al.*, 1998). It has also been shown that blinding reviewers as to the identity of authors decreases the rejection rate, and even more so if editors make sure that no reviewer reports on authors they may know personally (Godlee *et al.*, 1998). Additionally, if reviewers are asked to sign their reviews, rejection also decreases. Moreover, reviewers who have published extensively themselves produce better and more reliable reports. Investigating reviewers in the *BMJ*, it has been shown that editors were efficient in detecting good reviewers, taking into account what has been explained above.

It should be noted that blinding reviewers decreases the rejection rate but does not at the same time improve the quality of a review itself. Blinding seems to be a good technique to reduce bias, but further efforts need to be made to improve the reviewing process. Having reviewers sign their reports, thus making these reports public, also seems to be a good technique for, at least, putting an end to the heretofore hidden status of this genre. There is also an overall tendency to accept these techniques within the medical community at large. In 1998, approximately 50% of reviewers did not wish to sign their reports or to have their reports made public. Nowadays, in the *BMJ* only 5% of reviewers maintain this position. It is likely that important journals will start to make their reviews known via official websites (Hagan, 2003).

Two issues remain open for further study in relation to peer review in medicine: the bias against non-U.S. researchers and the role of women in the reviewing process of top journals. It has been detected that U.S. reviewers favor U.S. submissions much more that non-U.S. reviewers (Link, 1998) and that the presence of women on editorial boards of highly ranked medical journals is not proportional to their presence in medical associations nor to the number of papers published by women in those same journals (Dickersin *et al.*, 1998).

Medical Discourse, Illness Narratives

L-C Hydén and P H Bülow, Linköping University, Linköping, Sweden

Introduction

During the past decades, the health field has become a battlefield where alternative concepts of illness, health, and treatment compete with the dominant traditions of Western scientific medicine. New health care practices such as complementary and alternative medicine have gained status. Etiological factors have come to include 'lifestyle' factors, as in the relationship between smoking and lung cancer or the relationship between stress and certain coronary diseases. Patients have access today via the Internet to sources of information that were previously unavailable to them and can approach their physicians with more knowledge and new demands.

As part of these changes, researchers have become interested in questions having to do with the relationship between, on the one hand, the patient and his or her illness and, on the other hand, traditional scientific medicine and its concept of diseases. In this context, the study of illness narratives has gained prominent status.

Research on the forms and functions of illness narratives has expanded rapidly since the early 1980s. Its development is marked by diversity in the theoretical perspectives and methods that are brought to bear on a variety of problems.

Illness narratives is a wide field encompassing interview studies of patients' narratives of illnesses, studies of the way that narratives are used in the interaction between medical staff and patients, and clinical studies of how narratives could be used by medical professionals in encounters with patients. Another field of study that has emerged is the study of written and published illness narratives; Hawkins (1993) called these pathographies.

Theoretically, researchers have been interested in the narrative as an opportunity to study the subjective experience of illness, the way in which identity is reconstructed narratively in the face of illness, and how the institutional context affects the relationship between medical professionals and patients. This is especially interesting in terms of power and the patient's ability to make his or her voice heard in the medical encounter. Thus, researchers focus on narrative structure and coherence, as well as on the functions of narratives in various social contexts.

Two Voices

A central problem area for many studies of medicine and illness narratives is the relationship between what is called the voice of the lifeworld and the voice of medicine. These concepts were introduced by Elliot Mishler in his book *Discourse of medicine* (1984). Mishler pointed out that in the discourse of ordinary medical interviews it was possible to discern two

different attitudes to the problems that patients brought to the encounter with the medical doctor. What he called "the voice of the lifeworld" is characterized by a biographical contextualization of the events and problems of patients' lives. Problems and problematic events are taken at face value and related directly to the patient and his or her actions and experiences. In contradistinction to this, 'the voice of medicine' is characterized by a scientific and critical attitude; events and problems are removed from the biographical context and related to more general and abstract medical theories of diseases.

When these two attitudes were found in the same discourse or conversation, a conflict between the voices could be seen, instead of the voice of medicine being dominant. This struggle results in a disruption of the flow of discourse. That is, the patient tries to voice his or her view of things, whereas the medical doctor tends to ignore this while holding onto the voice of medicine. This leads to an 'objectification' of the patient and 'to a stripping away of the lifeworld contexts of patient problems.' As a result, the "form of discourse severely limits, if it does not exclude entirely, the possibility of humane medical practice" (Mishler, 1984: 128).

A similar point was raised by Arthur Frank (1995, 1997) when he argued that medicine "hails" ill people, categorizing them as patients with a certain disease and thereby placing them in a story told by medicine using medical reasoning. According to Frank, "many ill people find they cannot live the story, or just the story, that biomedicine tells of their illnesses; the need for a voice of one's own is a particularity of our times" (1997: 31).

This conflict between different attitudes toward illness-related events and experiences, i.e., the fact that patients and medical professionals view illness, health, and treatment very differently, is found at the heart of much of the research on illness and narrative. Researchers have focused on various aspects of this conflict and in the following we discuss three different strands of this research.

First, we focus on the way that ill persons use narratives as a way to understand illness and reconstruct their identity in light of the illness experience, i.e., illness narratives in the lifeworld of patients. Second, we discuss research on narratives in the encounter between the patient and medical professionals. This includes research on the use of narratives as a clinical tool, i.e., narratives in the encounter between the world of medicine and the lifeworld. Finally, we focus on the way in which medical professionals use narratives, i.e., the narratives in the medical world.

Narrative, Lifeworld, and Identity

Illness narratives, that is, stories about illness told by the ill persons themselves (as opposed to narratives about illness told by medical professionals (Hydén, 1997)), usually concern life-threatening diseases or chronic illnesses. This kind of illness commonly, perhaps always, influences the ill person's perception of self. A serious and chronic illness not only means a biographical disruption, it also means that life takes a new turn often totally unrelated to how life was before illness. According to American sociologist Kathy Charmaz (1983), chronic illness is diminishing to an individual's identity and sense of self and a fundamental consequence of illness is the experience of loss of self. This changed perception of self can primarily be described as a social interactional process that partly originates from the loss of social contacts that is inherent in illness and partly from the way that other people seem to regard ill persons and treat them.

Considering narrative as a powerful cultural resource for organizing, making sense of, and communicating experiences such as illness, the study of illness narratives becomes important for understanding phenomena such as identity and transformation of self due to illness. This holds true for oral as well as written stories and for what sometimes is called performed or enacted stories (Frank, 1997; Langellier, 2001).

Chronic illness is almost always undesired and probably beyond what a person has imagined his or her life to be. Being unexpected and unwanted, illnesses raise questions such as "why me?" and "why this?" These are questions that medicine is hardly ever able to answer in a clear, straightforward way.

In an ill person's endeavors to understand what is happening, narratives become an important resource for making sense of things. Narratives help to sort out and organize different kinds of experiences into a more comprehensible and coherent whole. Hence, it becomes possible to use narratives to connect events and experiences that did not seem to be related at the time they occurred. The connection can be used to explain illness.

Time is central to chronic illness. For one thing, it is a characteristic of a chronic illness that there is no immediate and certain cure and that such an illness thus can be part of the ill person's life for many years. Another typical feature of chronic illness is the insidious onset (Bury, 2000), which makes it difficult for medicine as well as for the ill person to know when the illness actually started. The difficulty of fixing the time of the debut has implications for issues of responsibility for illness and suffering. This

vagueness simultaneously offers the possibility of temporalizing illness and incorporating illness into the personal life story and thereby handling questions about blame and responsibility and ultimately the sense of self.

In a study concerning a medically unexplained illness – a contested illness exemplified by Chronic Fatigue Syndrome (CFS) – it was argued that the interviewees temporalized their illness in different ways. There was a discussion of what implications this had for questions about responsibility, blame, and freedom of liability (Bülow and Hydén, 2003). The analysis draws on the shadows of time concept, borrowed from literary historians (Morson, 1994). This concept involves events casting their shadows over the narrator's present. These shadows of time can come from the back (backshadowing, i.e., what one later thinks should have been foreseen), can come from the side (sideshadowing, i.e., alternative roads and ends), or can appear as a kind of vortex (i.e., when several events separated in time finally converge into illness).

The use of different time shadows (e.g., backshadowing) when telling one's illness narrative means that the ill person might blame him- or herself for not acting in a proper way in order to prevent illness or for not handling it differently. It can also mean the reverse, that the temporalization of illness might give the narrator limited or even total freedom from liability. In the study, this also became obvious in the way that interviewees used backshadowing by placing their illness back in time and simultaneously accounting for why they should not be blamed and in what way they would be seen as responsible persons. This could be achieved by making statements about an early visit to a doctor and describing the feeling of confidence in the results of medical examinations that did not indicate any disease and in the competence of the doctor who told the narrator not to worry. In so doing, the narrator presents him- or herself as a person who, even at the time he or she is describing, showed great responsibility. This way of telling the story of illness counteracts some of the questions that might be posed about possible actions to be taken.

Another way of managing illness narratively by using a medical diagnosis was shown by Lisa Capps and Elinor Ochs (1995) in an analysis of the stories told by a 34-year-old married woman about agoraphobia. The researchers showed how the woman created a master narrative "that holds for all her panic experiences, wherein anxiety is presented as an irrational response to being in an immediate activity setting" (Capps and Ochs, 1995: 80). The connection established by the narrator between the situations she finds herself in and the feeling of panic makes her think that a causal relation exists between the area in which she is not able to move and her anxiety. At the same time, she regards her own avoidance behavior as a token of being agoraphobic. Capps and Ochs demonstrated with a rigorous linguistic analysis that it was possible to interpret the panic attacks as a delayed 'no' to accommodate the situation in which panic later appears. The authors argued that the diagnostic construction provided the woman "... with a medical reason for neither accommodating nor even negotiating demands and desires imposed or promoted by others" (Capps and Ochs, 1995: 100). At the same time, she created a coherent story of her life.

Illness narratives are also important for the identity of the ill because of the way in which narratives and narrating work in gaining a new identity as a special kind of person. This transformation of identity might happen through learning to tell a new story about oneself, one's life, and the form of illness, often together with other sufferers. This emphasizes the social act of storytelling that is sometimes lost in narrative analysis. Research on self-help groups and patient associations are examples of this transformation of identity through storytelling in groups.

In her study of Alcoholics Anonymous (AA), American anthropologist Carol Cain (1991) indicated that narrating is probably the most important element for someone becoming a new member of the group. She argued that "identity reconstitution in AA takes place through reinterpretation, of self and of one's life, and that the major vehicle for this is the AA personal story." According to Cain, becoming a member of an AA group is about learning to tell a new story from prototypical narratives about life. This learning takes place by participating in collective storytelling. Within AA, there is a well-defined idea that it is the effects of drinking alcohol that constitute the problem and not the other way around. To become an AA member, one must adopt this view, which means that one must rethink the life one has lived and one's relationship to alcohol. Through what Cain called identity diffusion, the old identity is weakened. "In acquiring a new identity," she explained, "individuals must understand the identity, internalize it, and become emotionally attached to it" (1991: 218). This gives rise to stories resembling conversion stories in which the teller reinterprets his or her past in light of a turning-point experience.

Cain stated that it is the process of learning to tell his or her story with the appropriate structure that helps an AA member to understand him- or herself as an alcoholic. In this process, newcomers learn from old-timers to tell the story in the right way. Cain's

study indicated that the longer a person has been a member of AA, the more his or her story resembles the prototypical AA story. The major vehicle for the identity reconstitution process is thus the AA personal story. Such stories, which Cain described as a 'learned genre,' can be told at meetings in a formalized manner as well as being published in pamphlets and the like. By reading the stories of others and by hearing other alcoholics tell their stories at meetings, newcomers learn both the structure and the content of the prototypical AA personal story and at the same time these stories also provide a newcomer with experiences to compare with his or her own. This shows that learning to tell a new life story is something that people do together in social interactions.

Learning to tell a new story through interaction in a group such as AA shows a kind of enculturation – becoming a group member and gaining a new identity through this membership. This process partly differs from the idea of narrative as a means to articulate a voice of one's own and thereby resist a medical categorization. On the contrary, each member in an AA group adopts the collective identity of a nondrinking, recovering alcoholic by learning to tell the right story in the correct way.

Many chronic illnesses have an insidious, vague onset. This not only makes it difficult to describe at what point one's illness started, but also means that changes in the sense of self can constitute a very long process that is not always possible to follow in a single story. On the contrary, it might more often be the case that people describe changes in their sense of self and identity transformations through a series of stories. American sociologist Susan Bell has studied what she calls "DES daughters," i.e., women who were prenatally exposed to the drug diethylstilbestrol (DES), which increases their own risks of infertility, miscarriages, and vaginal and cervical cancer. In her study, Bell (1988) showed how a slow and gradual change in identity is narrated with the help of what she called linked stories. "Through linked stories, people explain how their experiences – and their interpretations of these experiences – have changed over time" (Bell, 1988: 101).

By reducing each story to its core narrative, it becomes possible to see how the several narratives, though not told in a direct sequence, are linked to one another through structure and content (Bell, 1988). Together, the multiple narratives describe a change in the attitude the woman has toward her illness. In her first story, she presents a rather distant and disinterested attitude in regard to the illness and the risk that this implies. In the second story, the consequences of being a DES daughter become obvious for the narrator. In a third narrative, she describes a political awakening and commitment that also includes an interest in other women in a similar situation. This gradual change also includes an altered view of medicine and physicians. Drawing on Mishler's (1984) voice of medicine and voice of the lifeworld, Bell demonstrated how the transformation is linked in the first two narratives to a confidence in the voice of medicine; she receives what she regards as reliable information about the illness from medical sources. In the third story, her trust in medicine has changed into a critique of medicine as the narrator criticizes the way that medicine treats the risks to which these women have been exposed. The narrator also criticizes the medical world for not providing the right information, for not preventing problems, and finally for prescribing the medication that caused the problem in the first place. According to Bell, "becoming political means balancing the voice of medicine with the voice of the lifeworld" (1988: 120).

Following Bell, Langellier (2001: 152) studied what she called "interpretive links" among the stories one woman tells about her experiences of having breast cancer. Langellier, however, emphasized "the performative struggle of identity" in these narratives by asserting that the full meaning of stories is **enacted** rather than semantic and "located in the consequences of narrative as well as its meanings" (Langellier, 2001: 175).

Narratives in the Clinical Encounter

In a study on the use of narratives in the actual encounters between patients and doctors, Clark and Mishler (1992) pointed out that narratives do not constitute a neutral instrument. Instead, there is a struggle in the encounter to determine which narrative about the patient's illness will be the dominant one – the patient's everyday narrative about the illness or the biomedical narrative about the disease.

In typical medical interviews, physicians either ignore or interrupt patients' everyday accounts of their problems. The traditional narrative presented by the medical doctor often has the form of a chronicle in which signs and symptoms are organized according to a biomedical plot but removed from the larger context of patients' lives. Patients try to restore the everyday context of their illnesses, locating symptoms within their daily experiences and observing the impact of said symptoms on how they function personally and socially. In order for the patient to be able to present these contextualized stories, a realignment of the relationship as it is typically enacted in medical interviews is required. The physicians must relinquish or at least moderate their dominance and move

toward becoming more attentive and responsive listeners, encouraging patients to tell their stories instead of imposing the medical plot of illness and cure.

In several studies, Young focused on the negotiations between various interpretative frames, for instance, between the world of medicine and the lifeworld. The patient visiting a medical doctor must relate in some way to the world of medicine (Young, 1997). Young stated that the patient can adopt at least two different strategies in relating to the medical dominance. The first strategy is – as Mishler pointed out – an attempt to break in against the voice of medicine and make the voice of the patient heard. This can be accomplished through ignoring, misunderstanding, or flouting medicine's conventions. The second strategy involves inserting a narrative enclave consisting of lifeworld experiences into the realm of medicine (Young, 1997: 33).

A case in point is Young's analysis of the encounter between a medical doctor and an elderly Jewish professor who arrived in the United States via Auschwitz in 1945 (Young, 1997, 1989). By telling stories to the doctor during the physical examination about the bodily injuries he suffered during his imprisonment in Auschwitz, it becomes possible for the elderly patient to sustain his own sense of identity – despite the fact that he is standing naked before his doctor. This narrative about his experiences in Auschwitz has the form of a narrative enclave inserted into the medical discourse. The narrative enclave is an alternate reality that makes it possible for the patient to reappear as a person in the midst of the medical world.

Several authors including Kleinman (1988) have pointed out that the illness narrative ought to have a central position in clinical medicine. He and several other researchers emphasized the importance of illness narratives as a tool by which doctors can acquire a more detailed clinical picture of the patient (Kleinman, 1988; Brody, 1987; Greenhalgh and Hurwitz, 1998). Narratives can also serve as active devices in therapeutic and clinical work.

In her work on occupational therapy, American social anthropologist Cheryl Mattingly (1994, 1998) described how health professionals try to shape a progressive course of treatments and recovery processes into a coherent plot – what she referred to as "therapeutic emplotment."

A basic problem in clinical practice is how to insert therapy in some meaningful way into patients' lives. Therapy as a clinical practice could be conceived of as a sequence of actions directed **at** the patient. This may work in certain contexts but in other contexts the clinician must work **with** the patient – especially with chronically ill patients. This means that the clinician together with the patient must give the therapeutic actions a shared and common meaning. Mattingly pointed out that this can be accomplished by the healers actively striving to shape the therapeutic events into a coherent action organized by a plot. In this sense, telling narratives in the clinical context becomes a form of social action.

Placed in a narrative context, physical dysfunctions or the daily tedium of routine rehabilitation may take on new meaning and thus become endurable. This form of therapeutic emplotment may also influence or change the patient's time horizon for the course of the illness, by establishing a link between the medical interventions and the trajectory of recovery and engendering hope of eventual cure.

Rita Charon (2001) argued for the development of a "narrative medicine," emphasizing the physician's expertise in absorbing, interpreting, and responding to patients' stories. The doctor must learn the process of close, attentive listening to the patient in order to hear the patient's narrative questions, but also to recognize that there are often no clear answers to these questions. Through attentive listening, a relationship is created that allows the physician to arrive at a diagnosis, interpret physical findings, and involve the patient in obtaining effective care.

Narratives, Medical Knowledge, and Experience

It is not only those who are sick who use narratives to understand illness and suffering; narratives are central to the medical profession as well. The case stories published by Sigmund Freud are proof of this argument. In the practical, clinical context, narratives and storytelling are also part of the creation and communication of knowledge about illness and suffering in the processes of "constructing cases" (Atkinson, 1995) and telling "doctor's stories" (Hunter, 1991). It is probably not surprising that narratives play such an essential role in medical practice, since medicine is partly based on descriptions of people's illnesses and suffering.

Medical professionals use narratives to make sense of illness in their work. In discussions between colleagues, stories seem to be crucial to creating patterns and to defining and reaching an agreement on what kind of illness one is dealing with and the best way to describe it. This means that stories are part of medical practice as well as of the creation of medical knowledge. Thus, both the study of illness narratives and narratives about illness (Hydén, 1997) function as a window into how people create an understanding of their own suffering as well as others' suffering.

In many ways, medicine is a communicative enterprise although the stories told by the patients constitute just a small part. British sociologist Paul Atkinson (1995: 90) wrote that "the cynical observer" might speculate that patients' complaints about their suffering are rather "the pretext for medical talk." Narratives become part of medical practice through such medical talk. Medical knowledge is created and re-created through a range of communicative activities – oral as well as written – between colleagues. The medical world is composed of, and exists partly through, reports, documents, clinical rounds, and conferences. It is possible to regard all these forms of collegial 'talk' from a narrative perspective since stories and storytelling are included in different ways.

In his microsociological analysis of medical collegial talk, Atkinson (1995), drawing on what Elliot Mishler (1984) called voices, identified several voices of medicine representing various, and sometimes even competing, modes of medical knowledge. These are, for instance, the voice of science, which articulates knowledge "warranted by an appeal to research such as published scientific papers" (Atkinson, 1995: 131), and the voice of the eyewitness, which represents what a physician or a student physician has seen and done in relation to a certain case. In contrast to the latter, in which "the doctor stands in a personal relation to the knowledge" (1995: 131), Atkinson described the voice of personal experience, which is, at least when expressed in narrative ways, "almost exclusively the prerogative of senior physicians" (1995: 147). Even the nature of seniority, Atkinson argues, is partly established by the right to tell this kind of story.

These different voices are used in the presentation of cases and thus become part of the stories told at clinical rounds and conferences. In accordance with the struggle between the voice of medicine and the voice of lifeworld that Mishler (1984) emphasized, Atkinson (1995) noted asymmetries between different voices of medicine. Not only are the narratives from the voice of personal experience told exclusively by senior physicians, but the voices of students and younger colleagues can be interrupted and fragmented by questions from senior physicians. Similarly, the voice of personal experience commonly includes laboratory findings and thereby also a more scientific voice of medicine.

Through Atkinson's study, the crucial role of narratives and storytelling for voicing and managing different opinions as well as domains of credibility and for the learning of medical knowledge becomes obvious.

Hunter (1991) studied how physicians use narrative forms to present cases in patient rounds, case conferences, and medical charts as modes of communicating medical knowledge to both colleagues and students. She argued that the narratives of medical doctors tend to focus on unusual or deviant instances of disease signs and processes, thus emphasizing the features of particular cases within the general framework of what is known about different types of disease and their typical forms of appearance. This narrative strategy expresses and supports a pragmatic and instrumental orientation to the treatment of patients.

Summary

Narratives and storytelling serve important purposes in creating knowledge about personal illness for clinical practice, in constructing medical knowledge, and in teaching about illness and suffering. With the help of illness narratives, the individual can explain, legitimize, and manage experiences and actions that are difficult to understand by using, for instance, a medical diagnosis as the frame of explanation. Likewise, narratives are used in collegial talk to construct cases and to deal with opposite opinions as well as various modes of medical knowledge. Through enacted or performed illness narratives, ill persons or their relatives can oppose the story that medicine tells about them by the way that they narrate their actions rather than by their experiences of illness. This means that narratives are crucial to creating a coherent story, whether it is the story of one's life or the case story of a patient that is at stake.

Medical Discourse: Non-Western Cultures

The term 'shaman' has its etymological root in the word 'saman' from a Manchurian language, meaning 'one who knows.' Originally the term was used in various areas of northern Asia and was later brought to the Americas, to the southeastern part of India, and to Australia and Africa. According to Mircea Eliade, shamanism or the socially specific role of the shaman was brought to the Americas by the first eastward waves of immigration from Asia. The origin of the shaman in America (the continent in which the role has been most studied) is well documented (see Eliade, 1974: 266; Lowie, 1934: 183–188).

The role of the shaman is not limited to individual practice. It is currently portrayed in the literature as a category of social activity with a legitimate function as a health care phenomenon. Classifications include legal aspects, health program functions, adaptation in the migration of ethnic groups, and shamanic practice in the integration of tribal peoples and their customs into the social mainstream. As such the role of the shaman has become an interdisciplinary study.

Elaborations in the area of anthropology and ethnopsychiatry have focused on therapeutic aspects and role models which include the magical or nonlocal physical aspects of shamanic activity. These include Geza Roheim (1950), Mircea Eliade (1951), Claude Lévi-Strauss (1958), Alfred Métraux (1967), George Devereux (1970), and others who treat aspects of hypnotic suggestion or trance as therapy.

Mircea Eliade: Ancient Techniques for Producing Ecstatic States

Eliade is the great classic authority on shamanism, and is recognized as such by those who wrote after him. His *magnum opus* (*Shamanism and the ancient techniques of extasis*, 1951) is the first attempt to comprehensively approach the subject from the point of view of a religious historian. His sources include works on what is described as classical shamanism in Siberia, the Americas, Indonesia, and Oceania.

Mystical experience is central to his theme, in which he emphatically rejects the proposition of

Medical Discourse: Communication Skills and Terminally Ill Patients

I G Finlay and S Sarangi, Cardiff University, Cardiff, UK

Introduction

Recent years have seen a strong drive for the teaching of communication skills at undergraduate and postgraduate levels of medicine in the United Kingdom. Many studies, particularly of doctor–patient interactions, have objectively supported the need for skills training, especially as health professionals' attitudes have been changing toward patients' psychosocial needs (Fallowfield *et al.,* 1998; Royal Society of Medicine, 2000). The National Health Service, in seeking to better inform and understand patients' needs, has sought to develop a paradigm of interaction that assumes of, or imposes upon, doctors and nurses the necessary 'communication' skills (SUPPORT, 1995). Problems with communication are recognized as being not only a major source of anxiety for patients and their relatives but also a common source of complaints and litigation; about 90% of the complaints that reach the NHS Ombudsman are attributed to poor communication between the health care professional and the patient and/or his family. Within a culture of blame and litigation, and with many patients having unrealistic expectations of clinical care, the doctor can also fear accusations of culpability, even if the patient's disease has progressed beyond the bounds of clinical science.

The training and assessment of communication skills in the medical curricula has been consolidated since the General Medical Council produced its document 'Tomorrow's doctors,' which specifically outlines the core requirements of any undergraduate curriculum. At the undergraduate level, the curriculum has become increasingly crowded as medical science advances and medical students need to be familiar with a bewildering amount of rapidly advancing knowledge. Some have claimed that medical training is being compromised as a result (Williams and Lau, 2004) and that communication skills are inherent in the student upon entry to medical school, with very little cost-effective change from teaching.

This recognition of the importance of effective communication has also driven the formal assessment of consultation skills in professional examinations, often using trained actors to simulate patients in an attempt to achieve a uniform assessment standard. The drive to teach communication skills at the postgraduate level has gathered momentum in the secondary and tertiary care sectors in recent years. General practice training in the United Kingdom has incorporated communication skills training and assessment for over 20 years, yet only half of general practitioners report having had training to prepare them to communicate with the terminally ill (Barclay *et al.,* 2003).

The importance of the quality of information giving that is required to ensure that patients can make informed, competent, voluntary decisions free of coercion is now being recognized in law. In the United Kingdom, the forthcoming Mental Capacity bill focuses on the wishes of the patient, with an assumption of capacity for decision making and a rigorous requirement for objective evidence to support the view that a person is not competent to be involved in making decision about his care. The importance of effective communication and assessment of true need is nowhere more stark than when the patient requests death to be hastened or refuses consent to treatment.

In the terminally ill, the desire to shield patients from the reality of their situation and avoid causing heightened anxiety often leads to poor truth telling and nondisclosure; importantly, this has been shown to usually create even greater difficulties for patients and their relatives, as it denies them the opportunity to reorganize and adapt their lives toward realistic goals (Fallowfield, 2002). Having better understanding of the nature of this important area of communication should not only improve the quality of the patients' experience and clinical care but also improve the decision-making process, and hopefully might lead to a reduction in complaints (and possibly litigation). An additional benefit of good communication skills training may be a decrease in work-related stress, as staff often report feeling inadequately prepared to deal with patients who are dying and their families.

The Ethos of the Terminally Ill

Terminally ill patients are particularly vulnerable, often having a heightened awareness and sensitivity to those around them. They are vulnerable by dint of facing death, and they are also vulnerable precisely because of their disease (Christakis, 1999; Seale, 2000). Infection, metabolic disturbances, cerebral disturbance by metastases or ischemia, and the effect of medication can make patients confused and less able to cope with new information, thus impairing their competence.

Their families are also distressed and keen to minimize the distress experienced by the person they love

– the patient. Clinicians are in a difficult position as well. They may have spent months or years advising and taking a patient through grueling investigations, treatments, and interventions in the hope of achieving a cure or disease control. When these efforts fail, the clinician can feel a sense of personal failure, making it difficult to remain strong and supportive of the patient. Attempts to keep up a strong front are then interpreted as indifference by the patient and/or his family.

Distress in terminal illness is multifactorial, with overlap and interaction between the domains of concerns: physical, emotional, social, and spiritual. Problems intermingle, amplifying each other and enhancing the overall distress felt by the patient, to the point that the concept of Total Pain, coined by Cicely Saunders (Saunders, 2000), is experienced by those whose needs are not addressed. The physical assessment of symptoms will depend on taking a history, often in a semistructured way, examining the patient physically, and investigating further as appropriate with blood tests and so on. However, assessment of the concerns, fears, beliefs, and wishes of the patient requires a much more subtle interactional approach that depends on detecting cues, demonstrating empathy by reflecting comments in the language the patient uses, and presenting an overall nonverbal demeanor of active, engaged, and nonjudgmental listening.

In the terminally ill, patients' needs fall into the broad categories of: a decrease in functional status or activity; role change; symptoms, particularly pain; loss of control; financial burden; and conflict between wanting to know what is going on and fearing bad news. There have been studies of information giving in those with a poor prognosis, usually relating to the imparting of bad news (Kutner, 1999). These needs are broad in scope, not particularly associated with any specific patient characteristic, and therefore underline the need for careful individual assessment.

For patients with a terminal illness, the diagnostic or prognostic news received in an outpatients' clinic can be devastatingly traumatic; they are suddenly aware of what lies ahead of them, including the unavailability of cure, the uncertainties about how the illness will develop over time, the long-term and short-term side effects that any treatment regime might inflict, the impact of their situation on those they love, and the extent to which family relations might become affected, to name a few issues.

Much research about the terminally ill has focused on the perceptions of relatives, their judgments and evaluations of the care given. Remarkably little has concentrated on the needs of children and teenagers as relatives. Children have different adapting styles closely related to emotional development. Although beyond the scope of this article, the topic is in urgent need of good and sensitive research to guide clinical services.

A cancer patient's deficit in his quality of life has been defined as the relationship, in terms of a gap, between his expectations and the current reality experienced (Calman, 1985). Yet no health care professional can narrow this gap without really understanding a person's hopes, expectations, and the complex nature of their current distress. Hence, the quality of interactions of the patient with various health professionals will inevitably become a key influence on his quality of life.

Many of the communication issues explored in these studies, especially the tensions between the 'medical' and the 'social' in the delivery of bad news, communicating risk, decision making, and so forth, are important areas for future inquiry in hospice and palliative care patients.

Communication Issues Specific to the Terminally Ill

Although the quality of clinical interaction is seen as important in training professionals, the quality of interaction has not been a topic of inquiry in its own right. From a discourse/communication perspective, there is a large body of doctor–patient communication studies, but these have been mainly limited to general practice. Most health care studies in the sociolinguistic communication tradition have mainly engaged with the general practice setting, with their analyses being doctor-oriented and focusing on the structural organization of the consultation process. Very few studies deal with cancer clinics and care centers or focus on the life history of patients or their cumulative interactional experiences.

There is now widespread recognition that "the quality of clinical communication is related to positive health outcomes" (Simpson *et al.,* 1991) and that the same holds true for cancer care: "inadequate communication may cause distress for patients and their families" (Fallowfield and Jenkins, 1999; Fallowfield *et al.,* 1998).

Specific difficulties encountered in discussion with the terminally ill relate to prognosis. Before information is given, the clinician must assess how much the patient already knows, and what he expects will be the likely course of the disease and its accompanying problems. Some patients may have witnessed poor care or distressing death in others. Others may have guilt about issues in their own life, blaming themselves for the illness or viewing it as some type of retribution for past deeds. Family conflicts, varying

expectations from health care, and emotions such as anger, denial, or guilt are powerful influences on communication.

Although to the dispassionate pragmatist the situation may feel hopeless, the vast majority of patients can cope better with reality if they have something to hope for. However, such hope must be realistic – it must be the patient's own wish and arise from his aspirations rather than from the imposed values of others. An example is the patient who knows he is dying but hopes to be alive for his son's wedding. Knowing that every effort will be made to achieve that goal will instill realistic hope, which is preferable to reiterating the obvious but more pessimistic view that in reality a sudden catastrophic event such as an embolism may occur at any time, and so he should not hold out too much hope!

Quality of Information

Many studies have been concerned with information giving (Davison *et al.,* 2004; Friedrichsen and Strang, 2003; Walsh and Nelson, 2003), attempting to evaluate the patients' understanding of their situation as a proxy measure of the quality of the communication, rather than assessing the interactional data within a consultation. Such studies fail to recognize the varied competencies of those who are frail and ill, the differing individual contexts of their lives and their diseases, and that emotional factors can act as a powerful block to the patient being able to retain information, even if the clinician is normally skilled at giving information. The studies also fail to assess the information needs of the patient, often omitting assessment of the patients' perception of the issues they feel rightly concern clinicians and those they feel would be viewed as trivial by their doctor. Patients' past experiences, beliefs, and background knowledge are powerful influences that must be recognized in order for information giving to be effective and sensitive.

Accurate information is crucial to decision making. The powerful influence of the doctor cannot be underestimated – hope, concern, and realistic optimism are powerful feelings that suffuse a consultation and are absorbed by patients. By contrast, a pessimistic outlook is rapidly detected and can lead to hopelessness, despair, loss of a sense of dignity, and demoralization of the patient (Chochinov *et al.,* 2002; Kissane *et al.,* 2001).

There are two groups of studies: (1) those dealing with information the patients need/want; and (2) those addressing the quality of interaction between patients/their families and health professionals, seen as information exchange. The studies have used questionnaire and interview methods and have suggested that patients prefer interview, particularly in the home setting (Montazeri *et al.,* 1996a; Montazeri *et al.,* 1996b).

Studies of information needs of cancer patients in general (Christakis and Lamont, 2000; The *et al.,* 2000; Montazeri, 1998; Billings, 2000) confirm that most need clear information about diagnosis and treatment. According to Sell *et al.* (1993), 92% of patients required a truthful disclosure of diagnosis, but 26% of patients indicated a lack of information about prognosis. A recent large-scale questionnaire study (Jenkins *et al.,* 2001) also showed that 87% of the 2331 patients wanted all possible information concerning their illness and treatment. Gamble (1998) elicited patients' experiences and reported variations in individual patients' need for information and their perceptions of "insufficient information about the side effects of treatment."

More information *per se* is not the solution. Information must be contextualized, and its understanding depends on the prior knowledge base of the recipients, who are usually the patients and their family members. There is some evidence for variable communication with cancer patients and for their dissatisfaction (Royal Society of Medicine, 2000). Quirt *et al.* (1997) used a combination of interview and questionnaire to elicit both cancer patients' and professionals' views about the extent of the cancer, the intent of treatment, and the risks and benefits of treatment. Despite some agreement, the researchers found significant discordance between the understanding of doctors and patients of the extent of disease and intent of treatment. There was an indication that patients' lack of understanding of their condition could impair treatment decisions.

Only a few studies have engaged explicitly with prognosis and quality of life issues. Leydon *et al.* (2000) used interviews to investigate information-seeking behavior in a small study of 17 patients with a variety of cancers. They found that, as part of the coping strategy, patients may choose not to obtain further information about their condition based on 'faith,' 'hope,' and 'charity.' 'Hope,' or 'false optimism about recovery' may be seen as an overriding principle that guides patients' reluctance to talk about prognosis and its impact on their quality of life (Christakis and Lamont, 2000). Montazeri *et al.* (1998), in an interview study of 82 patients with newly diagnosed lung cancer, commented that "proper communication remains limited."

A case study by The and colleagues (2000) has looked at the whole trajectory of illness; this concentrated on patients with small cell lung cancer and the issues of collusion about prognosis and

of false optimism. However, the findings of Sell *et al.* (1993) and Jenkins *et al.* (2001) differed; these researchers found that patients and their family members may even interpret the term 'treatment' in a curative rather than palliative sense. In a follow-up study, The *et al.* (2003) explore the reasons underlying 'false optimism' and suggest how radiographic images as clinical evidence are given priority over interpretation of subjective bodily sensations as a way of coming to terms with the illness trajectory. This supports the change in clinical awareness that quality of life assessments should prioritize palliation of symptoms, psychosocial interventions, and understanding of patients' feelings more than duration of survival (Billings, 2000; Girling *et al.,* 1994).

Most of these studies overlook the interactional dimensions of what actually happens in a given clinical setting.

Quality of Interaction

For thematic analysis, we will regard Quality of Interaction as constituted in psychosocial/relational and biomedical/procedural dimensions. The longstanding distinction between doctors inhabiting "the voice of medicine" and patients inhabiting "the voice of the lifeworld" may be a useful starting point (Mishler, 1984). With older patients, social and relational issues often assume greater significance. Nurses are more likely to embrace a social/relational style when dealing with patients (Fisher, 1991). The decision on the part of doctors to focus on the biomedical dimension (e.g., treatment options such as chemotherapy and the treatment schedule) at the expense of the psychosocial/relational implications of a diagnosis is very much embedded in Western medical practice, but it is driven by the need to ensure that patients' consent to treatment is realistically informed by the choices available and the probable outcomes of each course of action.

Barton *et al.* (2005), in their study of end-of-life discussions in surgical intensive care units in the United States, identify four phases: opening, description of current status, holistic decision making, and logistics of dying. Of particular significance is the second phase, description of current status, where a shift from therapeutic to palliative care has to be accomplished discoursally. This also happens to be the phase where delivery of bad news (Buckman, 1992) has to be strategically managed (not in the diagnostic sense, though). Barton *et al.* (2005) thus complement Curtis *et al.* (2002), which is geared toward a content-based analysis of physician contributions in these end-of-life discussions.

Iedema *et al.* (2004), drawing upon data from Australian multiprofessional team meetings, focus on professional self-presentation and pay attention to the tension between the medical worldview and that of the dying patient. Studies in the UK context include the geriatric clinic (e.g., Coupland and Coupland, 1998), where the framing of family-relational issues become significant in the care of the elderly.

Styles of Involvement in Patient-Centered Palliative Care under Examination Conditions

In this section we outline a pilot study under examination conditions (Cardiff University Diploma in Palliative Medicine). We shift attention from labeling of itemized skills such as 'open questioning' or 'active listening' to an understanding of how consultations are interactionally achieved by using a discourse analytic perspective. In broad terms, discourse analysis focuses on the jointly constructed process of interaction as it pays attention to the multifunctional, context-specific nature of language use.

Styles of involvement at the communicative level are manifest at various levels of linguistic choices and interactional trajectories. At the linguistic level, degrees of involvement can be signaled through selection of pronouns, preference for active or passive agents, choice of modalization and lexicalization, and so forth. At the interactional level, features such as overlapping talk, ellipsis, other-initiated turn-completions, and perspective display sequences are indicative of conversational involvement. Our analytic focus will be on how doctor–candidates interactionally orient to their actor–patients, with particular reference to history taking and care/treatment management. We offer a distinction between 'recycling of patients' words' and 'reformulation of patients' words' and suggest that these styles elicit different accounts of patients' experiences and expectations.

The data consists of transcripts of audio-recorded sessions of simulated consultations within the Cardiff Diploma in Palliative Medicine. The analysis is carried out in two phases using the discourse analytic methodology of interactional mapping and thematic staging. In conclusion, we discuss the implications of such microanalytic analysis for validating assessment and for raising professional awareness.

We adopt a discourse/communication perspective, focusing on information exchange structures, use of rhetorical strategies, management of interactional role-relationships, and so on (Sarangi and Roberts, 1999). For current purposes, we draw upon what may be called theme-oriented discourse analysis (Roberts and Sarangi, 2005) based on interactional

mapping (Roberts and Sarangi, 2002). Of particular interest in the palliative care context is the notion of topic, i.e., how topics are navigated following a schema in patterned ways (Chafe, 2001).

Thematic Maps in Palliative Care Consultation

Theme-oriented discourse analysis draws upon a number of concepts from linguistics and social sciences. The following list, suggested by Roberts and Sarangi (2005), can be applied to the palliative care setting.

- Interactive framing: Framing is a filtering process whereby issues of concern to each communicant are either brought into their 'frame' or are discarded from the focus of the interaction (Goffman, 1974; Goffman, 1981). The priorities of each party will determine the frame and its content – for example, the doctor may be focused on physical symptoms, so that descriptors of pain and other physical changes will remain in the frame, but expressions of concern for the distress that this illness is causing to the patient's child may be discarded. By contrast, the main concern of the patient may be the child, with the awareness of physical symptoms acting as a reminder and marker of impending death and the herald to bereavement for the child. Within their shared frames there is little true overlap. When the problems are listed together, understood by both, and shared, the quality of the interaction is perceived to have improved (Roberts and Sarangi, 2003).
- Contextualization cues and inferences: These are the linguistic and prosodic features that invoke the context of each utterance to give it meaning. They channel the inferences in a particular direction by calling up the frames and affecting the footing of each moment of interaction (Gumperz, 1982; Gumperz, 1992). These features include intonation, stress, pausing, and rhythm, which tend to be used unconsciously and usually are unnoticed in their role of establishing or reinforcing social relationships. For example, the clinician encourages disclosure of a previously unsatisfactory consultation by use of 'mmm' in a nonjudgmental tone, and then follows with 'that seems to have angered you.'
- Face and face-work: In an attempt to 'save face' in an interaction, the person perceived as weaker or more vulnerable – the patient – will use politeness as a strategy to establish closeness and engage the empathy of the more powerful person – the doctor (Brown and Levinson, 1987). Thus, the patient will be hesitant to disagree with the doctor, even when in fact the doctor has failed to grasp the patient's priorities in the situation. This, is starkly seen when the doctor uses closed or rhetorical questions: 'is your pain better?' 'your pain seems better, doesn't it?'; to which the patient agrees before hesitantly adding a qualifier such as 'yes – a bit – but it still gets bad as the day goes on.'
- Social identity: Gender, social status, regional and ethnic background, and many other influences affect a person's social identity. These preexisting factors are brought to the consultation, but the way one person behaves to another will influence the social identity – the performed social identity (Erickson and Schultz, 1982) – of each during the course of the consultation. Thus, the patient who finds he comes from the same village as the doctor will feel closer and assume greater empathy than the patient who is racially different from the physician and who speaks with a very different accent. In both cases, such assumptions are reinforced or dispelled by the nature of the interaction itself, thereby increasing or decreasing the patient's sense of comfort with and confidence in the doctor. An important factor is the time that each is allowed by the other to speak – as a general rule of thumb, the doctor does well to spend about 80% of the consultation time listening and only 20% speaking, thereby affording the patient a sense of respect and encouraging the patient to disclose anxieties.
- Rhetorical devices: Rhetoric is the language used to influence or persuade, usually in a political context. However, in the consultation, such devices can be parallel syntax, repetition of lexical items, metaphor, analogy, reported speech, and lists. For example, the patient may describe various symptoms, including pain that is 'terribly sharp out the blue, makes me bend double . . . gets me down,' to which the doctor may reply 'sharp . . . like a knife' or may summarize with a list of the symptoms just reported and then check back to ensure that nothing has been omitted. This makes the patient aware that the doctor has understood the patient's agenda of problems to be attended to.
- Analysis of the consultations showed that those deemed effective by validated scoring, when used for assessment, also had specific features in discourse analysis. High scoring (effective communicator) consultations demonstrated that the doctor verbally dominated for a much shorter time (about 20% of the time); used lexical reflective statements early to encourage disclosure of problems; summarized issues demonstrating coinciding frames from the patient's concerns and the items afforded attention by the doctor; and used contextualization cues that encouraged the patient to disclose concerns.

Extract A [D = female doctor; P = female patient]

1 D: [. . .] your oncologist thought it would be good to come and see me and I just wondered what you why you were coming to see me
2 P: uhm (.) well basically it's because my hip's still giving me pain I'm getting problems with my breathlessness it seems it seems to be almost getting worse and uh walking is becoming difficult and oh I mean it's just (.) I don't know where to start really but .hh I ju – I need stronger painkillers the tylex isn't doing particularly much you know taking away the pain (it's almost making me worse) but then I get constipation and nothing else even gets rid of that (^^^^^^) even though I tried prune juice and you know the normal kind of remedy
3 D: can you tell me who started you on tylex
4 P: my GP I think yea
5 D: I see
6 P: yea it does take some of the pain away but I'm not taking them I (take probably) eight a day but it's sti:ll it's still becoming quite a strain to almost sort of get through the day and I don't know what's happening and there seems to be so much going on and I really had – when I went to Birmingham I was like *so* full of hope and everything else and then suddenly it's like no and it's just all come as a bit of a shock as well to me
7 D: so thinking about what you've just said you said it's all come as a bit of shock you wanna just tell me a bit more about that
8 P: ((crying voice)) well I thought I was gonna get treated I thought I was gonna to be okay and now just from what I can gather I'm just not going to be okay and I don't know how long I've got and what I'm doing or where I'm-I mean where I'm even going you know I just ((crying voice)) I even had hopes of going to university so ((crying voice)) (^^^^^) be realistic so we even uhm ((crying)) my my family and I were (^^^^^^) and I mean they know that I do have this pain and I know and dampen it down for them and I think they know that so they think it's probably even worse than it is =
9 D: mhm
10 P: = and (.) oh it's just ((crying voice)) I don't even like talking about it with them because they just get worried and they (can do nothing either) then there's no one to talk to and I don't know what's going on and it's just becoming really really (.) ((crying)) just stressful
11 D: (^^^^^^^^^^^)
12 P: (^^^crying voice renders words inaudible^^^)) and now my painkiller is not even doing very much for me so now I'm at a point where I'm rapidly going downhill
13 D: (^^^^^^^^^^^)
14 P: yes so it's mainly about about the painkillers really [uhm if I can have any stronger ones
15 D: [is it about the breathing as well
16 P: yea I am quite breathless just in everyday life uhm walking becomes more and more difficult uhm because of the breathlessness and I I find it very difficult to exercise you know and I've got the pain in my hip as well so to be honest
17 D: hm
18 P: I <u>never</u> exercise
19 D: okay (1.0) (^^) when (.) when did this when did they say there was no treatment
20 P: ((crying voice)) it was about a month ago a month and a half ago when I went up to Birmingham
21 D: (and then you went)
22 P: ((angry voice)) well I had two days of tests up there and then they suddenly went well no actually we don't – no we can't do anything for you because you've got problems with your lung (2.0) and up until that point I really thought ((emotional voice)) I really thought that I was going to be okay
23 D: so it was a complete shock
(2.0)
24 P: yea
25 D: what about your family
26 P: uhm (1.0) oh uhm (2.0) they know they know that I am not going to get treated they don't know how long I've got and neither do I ((emotional)) you know there's something inside me you know it's just <u>so</u>: frightening to think it's taking over my my life and my body and that its it's gonna end [it's just it's just so
27 D: [it's hard isn't it to be (^^^^^^) isn't it
(1.0)
28 P: ((crying voice)) I don't even know <u>when</u> I've got <u>no</u> idea and (^^^^^^^^^^) and uhm yeah my family do know you know they love me and they are very supportive and helpful but they are just so worried that I don't wanna worry them more
29 D: mhm
30 P: and you know they've problems of their own to deal with not <u>major</u> ones but you know they've gotta go through life and it's just
31 D: is there (^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^)
32 P: no I think it's I think it's my fault I know it's a big strain on (my) marriage ((cries)) (^^^^^^^^^^^^^^^^^^^^^^) (and for me)
33 D: have you got anybody to talk to
34 P: ((crying voice)) not really
35 D: any support?
36 P: ((crying voice)) not really no well my family <u>are</u> supportive they are I just don't like
37 D: you don't like
38 P: talking to talk to them it's not their fault it's more it's more me not wanting to say anything
39 D: mhm

Key analytic points: D seems to be following the flow of topic as P wishes to develop it; P is given adequate interactional space to cover her major concerns, ranging from coping with painkillers to frustration with the medical personnel to family

support. At crucial points D summarizes the key issues (turn 7, turn 15, turn 23). Most of the doctor's questions are derived from what the patient has said (e.g., turn 19, turn 25, turn 27, turn 33). The minimal responses throughout help the patient to reveal all her concerns, unhindered. In a sense, this flexible approach allows the doctor to get a sense of P's priorities and major concerns before responding in any definitive sense.

Let us consider a second extract from the same setting, but with rather different thematic/interactional development.

Extract B [D = female doctor; P = male patient]

1 D: I'm Dr (first name last name) and I work with the (symptom) control team that work here at the hospital and Dr Bloggs has dropped me a short note just to ask me to (^^^) see you and give us an opportunity to look at how you are at present
2 P: yeah
3 D: what would really help me if you could give me a little more background about what's been happening how you've come to where you are now
4 P: yea (^^^^^^^) yea about a year ago I uhm I was diagnosed with a cancer in the hip and uhm I get a lot of pain from that
5 D: hm
6 P: and uhm I was I had chemotherapy for six weeks a:nd I was all geared up to go for surgery (^^^^^^^^^^) a:::nd uhm I went up to Birmingham for that =
7 D: mhm
8 P: = and (.) and then on the day of the operation they went and canceled it =
9 D: right
10 P: = and uh said that I wasn't that the problem was it was probably my lungs
11 D: it must have been a big shock for you to have got all geared up for your surgery
12 P: yes that's right°it was°
13 D: and what problem were they explaining you had with your lungs?
14 P: well uhm they were sort of saying that the cancer had spread into the lung uhm (.) that was it
15 D: you'd been expecting that to be a possibility? were you warned that that might happen?
16 P: well no
17 D: hmm okay how long ago was that that you should have had your surgery? that was actually very [recent was it?
18 P: [that was about a month ago
19 D: ri:ght (0.5) okay how have things been in the month since then
20 P: uhm well not too brilliant uhm (0.3) a lot of pain uhm (1.0) and I just—I don't know what to (have) (0.5) what if (^^^^^) from that (0.5)
21 D: will you just (.) just hold on to that and let me find out just a little bit more about you that would just help me =
22 P: yea
23 D: = to to understand and how old are you now?
24 P: twenty
25 D: right and whereabouts are you living (^^^^)?
26 P: well I I live at home in XXX
27 D: right
28 P: uhm with my parents I am a student in uh in YYY uhm but I haven't been there for the last (0.3) eight months or so
29 D: hm the last year has been very much taken up with being ill (I would think
30 P: yea
31 D: yes do you have any brothers and sisters?
32 P: yea I've got one sister
33 D: and she is at home as well is she? (^^^^^^^^^^^) and how are your family been finding situation (.) have they been supportive to you or (^^^^^^^^^^^)
34 P: well they're worried sick
35 D: hm
36 P: uhm (1.0) my mother is uhm (.) supportive (^^^^) taken it in (^^^^^^)
37 D: right
38 P: and my father is (.) he does not really talk about it much (^^^^^^^^^^)
39 D: mhmm that is his way (^^^^^)
40 P: yeah I think so he doesn't really talk about it much
[Ten turns omitted]
51 D: yeah (2.0) and before you had the problem with your hip did you (^^^^^^^^^^) or (^^^^^^^)
52 P: it was a shock [5 min]
53 D: yes (2.0) oh (.) that's helpful for me to see if you have an idea of (.) to find out more about you (.) is there anything else you think would be helpful for me to know just to (^^^^^^^) bigger picture (^^^^^^^)
54 P: I just wonder (what to do next)
55 D: yea right
56 P: it's (^^^^^^^^)
57 D: yea (1.0) so shall we go back to (.) the pain which seems to be the main thing that Dr Bloggs asked me to see you about
58 P: yes
59 D: can you just give me a little bit more idea what's been happening with that
60 P: yes uhm well it's been getting worse really I'm taking all these painkillers =

Analytic points: D's style of questioning borders on hyper-questioning (see turns 11–33), which does not allow P to nominate or elaborate on what concerns him most. D's questions are partly unrelated to what P has just revealed. Some of the questions preempt the patient's experience (e.g., turn 29), expecting the patient to confirm or disconfirm. This style of questioning is very different from what we saw in Extract A. Overall, one gets the sense that here D is pursuing his own history-taking agenda, as evidenced in turn 21 ("will you just hold on to that and let me find out

just a little bit more about you"). Notice that D returns to this topic in 57 ("shall we go back to the pain"). In both extracts, patients' circumstances have been framed in the wider family context, but there are significant interactional differences across the two styles of topic involvement.

We have chosen to present the above two extracts that show contrasting styles of interactional involvement. Space does not permit us to offer a detailed discourse analysis of all aspects of the interaction, so we limit ourselves to a theme-oriented approach as suggested earlier. Having decided on the theme of involvement, we can notice that extracts A and B have different involvement patterns. Whereas in A the patient is allowed generous interactional space to narrate her concerns, extract B is characterized by a sequence of question–answer turns mainly around the doctor's agenda. Although both consultations explore the family support system, they do so very differently and give this theme differential priority in the interaction. Communication about the illness within the family setting receives due attention.

Quality of Life

Both the extracts above deal with quality of life issues, but they do so differently in interactional terms.

Quality of interaction has been given a separate emphasis from quality of life, which is affected by the quality of interaction. Quality of life is seen as functions in specific domains, with the aim of minimizing distress through attention to symptoms, psychosocial, and existential concerns.

Much of the patient disclosure relates to informing the physician of the factors that are impairing quality of life, and these factors form the basis of the areas to be addressed in the clinical management plan. The notion of 'quality of life' embraces almost everything, ranging from physical/functional and social/economic to psychological/spiritual dimensions. A useful operational definition of quality of life is 'the relation between expectation and experience' (Calman, 1984; Carr *et al.,* 2001). We assume that both life expectations and lived experiences are seen at the level of interaction. It is then possible to look for quality of life issues at the interactional plane, while allowing for individual variations. In the clinical encounter, different views of both expectations and experiences are bound to surface. We will be looking for the interplay of experience and expectation (i.e., quality of life) in terms of how past, present, and future scenarios are talked about. One research task will be to see the extent to which health professionals orientate their communication to the relation between the expectations and experiences of individual patients and how patients respond to such critical moments.

A distinction between quality-of-life outcome measures in clinical research and the management processes and communication issues that address quality of life in daily clinical practice is overdue. Given our focus on clinical practice, the following dimensions of communication need to be highlighted: identifying and prioritizing problems; facilitating communication; screening for hidden problems; facilitating shared clinical decision making; and monitoring changes or responses to treatment. We would suggest that a detailed study of quality of interaction can contribute to our understanding of quality of life measures. This is particularly relevant in the context of cancer patients, for whom quality of interaction with health professionals and family members prove critical to all aspects of personal and clinical decision making during their treatment and end-of-life care.

Concluding Remarks

In the introduction we challenged the possible contributions that language and communication research can make to health care practice. One option is what we have displayed here – collaborative interdisciplinarity (Sarangi, 2002). The other option is long-standing ethnographic involvement in the research site so as to understand the very setting and the professional roles and identities (Candlin, 2003; Clarke, 2003; Cicourel, 2003).

It does seem true that communication skills cannot be taught or researched generically by nonclinical experts alone, as they do not have a comprehensive understanding of the complexities of medical conditions and the various aims of a consultation. Although they may have specialized knowledge of language and communication, they may have little knowledge and understanding of factual clinical content, which is necessary for their analysis to be useful to practitioners. On the other hand, communication skills are usually being taught in a prescriptive and formulaic way, with no recognition of language and communication as a discipline (Sarangi, 2004). Although the quality of clinical interaction is seen as important in training professionals, the quality of interaction is not a topic of inquiry in its own right – but there is a pressing need to combine linguistic theory with clinical practice in the context of care giving.

Medical Discourse: Developments, 16th and 17th Centuries

M Gotti, Università di Bergamo, Bergamo, Italy

Introduction

The increasing need to use the English language for the expression of specialized texts caused a heated debate in 16th and 17th century England, as the adoption of other languages (Latin, in particular) was considered to be no longer sufficient for this purpose. The two centuries taken into consideration here are very important for the development of English medical discourse, as the years 1500–1700 mark a remarkable period of increasing use of the vernacular for medical and scientific writing. Indeed, at the beginning of this period, Latin still had a dominant role. Moreover, an analysis of the combination of Latin and English in late-medieval English medical manuscripts reveals code mixing as a widely exploited discourse strategy, one that implies a century of bilingual readership (Voigts, 1996). At the end of this period, English prevailed, and the process of vernacularization can be described as largely complete by 1500, when we can find a full range of sophisticated university treatises on medicine in English in which Latin plays little or no role. Indeed, of the 238 medical books published in the years 1640–1660, 207 were in English (Webster, 1975: 267).

Epistemological and Linguistic Changes

Great epistemological and methodological developments took place in that period, in both medicine and surgery; old scholastic thinking began to be replaced by new patterns of thought and new methodologies based on observation and interpretation of physical phenomena. These developments determined the need for corresponding changes both in the ways of communicating the new discoveries attained by means of innovative procedures and apparatus and in the expressive tool to be used to describe and argue about the new phenomena observed and analyzed. The evolution of the methods adopted in the study of medicine and the development of new surgical procedures indicated a change not only in the approach to the interpretation of the issues analyzed, but also in the way in which phenomena ought to be described and opinions expressed.

Criticism was made both of how language was employed in the various processes of medical research and, in particular, of the suitability of the tool itself for an accurate, precise expression of the concepts

Medical Discourse: Developments, 16th and 17th Centuries

M Gotti, Università di Bergamo, Bergamo, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The increasing need to use the English language for the expression of specialized texts caused a heated debate in 16th and 17th century England, as the adoption of other languages (Latin, in particular) was considered to be no longer sufficient for this purpose. The two centuries taken into consideration here are very important for the development of English medical discourse, as the years 1500–1700 mark a remarkable period of increasing use of the vernacular for medical and scientific writing. Indeed, at the beginning of this period, Latin still had a dominant role. Moreover, an analysis of the combination of Latin and English in late-medieval English medical manuscripts reveals code mixing as a widely exploited discourse strategy, one that implies a century of bilingual readership (Voigts, 1996). At the end of this period, English prevailed, and the process of vernacularization can be described as largely complete by 1500, when we can find a full range of sophisticated university treatises on medicine in English in which Latin plays little or no role. Indeed, of the 238 medical books published in the years 1640–1660, 207 were in English (Webster, 1975: 267).

Epistemological and Linguistic Changes

Great epistemological and methodological developments took place in that period, in both medicine and surgery; old scholastic thinking began to be replaced by new patterns of thought and new methodologies based on observation and interpretation of physical phenomena. These developments determined the need for corresponding changes both in the ways of communicating the new discoveries attained by means of innovative procedures and apparatus and in the expressive tool to be used to describe and argue about the new phenomena observed and analyzed. The evolution of the methods adopted in the study of medicine and the development of new surgical procedures indicated a change not only in the approach to the interpretation of the issues analyzed, but also in the way in which phenomena ought to be described and opinions expressed.

Criticism was made both of how language was employed in the various processes of medical research and, in particular, of the suitability of the tool itself for an accurate, precise expression of the concepts

reported. Those specialists who intended to use the native language in the expression of medical phenomena often pointed out its deficiencies and inaccuracies. For example, Borde often inserted Latin quotations in his work "for [he] nor no man els [could] not in theyr maternall tonge expresse the whole termes of phisicke" (Borde, 1552: 38^{v}). Similarly, Christopher Langton complained of the limited number of vernacular anatomical terms:

> I can do no lesse then count the negligence of our Phisitions to be the cause of [the lack of English anatomical terms]: for yf they had written of theyr arte in theyr mother tunge, as they do in other places, why shulde we lacke englysh names more then we lacke eyther Latyn names or Greke names? and yet to saye the truthe, it is better for vs English men to haue English names, then eyther Latyn or Greke. (Langton, c. 1550: Diii^{r})

Another criticism often made by specialists was the polysemy characterizing many words, which often made texts ambiguous. The remedy suggested consisted of the coining of new terms providing a stricter delimitation of meaning. Indeed, the coining of native terms – particularly frequent in case of translation – is often explained with the motivation of greater clarity; this is the motivation provided by Andrew Borde for his translation of "obscure wordes and names into Englyshe":

> For as muche as olde, auncyent, and autentyke auctours or doctours of Phisicke in their bokes doth wryte many obscure terms, geuinge also to many and dyuerse infyrmities, darke termes, dyffycyle to vnderstande, some and mooste of all beyng Greeke wordes, some and fewe beynge Araby wordes, some beyng Latyn wordes, and some beyng Barbarus wordes. Therfore I haue translated all soche obscure wordes and names into Englyshe, that euery man openlye and apartly maye vnderstande them. (Borde, 1552: Av^{r})

Coining New Terms

The field in which the English language proved to be particularly inadequate was that of 'names of art,' that is, of the technical terms that made up the basic lexis of a subject. This lack of specialized terms often made the translation of works into English an arduous task or made it difficult for English specialists to write essays in their native tongue. In the following quotation, for example, Robert Recorde points out the difficulties encountered in choosing to write in his native tongue:

> But now as touchyng myne entent in writyng this treatise in the english. Though this cause might seme sufficient to satisfy many men that I am an englysh man, and therefore may more easely and plainly write in my natyue tonge, rather then in any other: yet vnto them that know the hardness of the mater, this answer shuld seme vnlykely: considering that it is more harder to translate into such a tonge, wherein the arte hath not ben written before, then to write in those tongues that are accustomed, and (as I might say) acquainted with the termes of the science. (Recorde, 1547; quoted in Jones, 1953: 73)

The realization that the English language was inadequate for medical purposes led to its gradual amelioration, from both a quantitative and a qualitative point of view. Specialists made great efforts to increase the number of specialized terms and improve the exactness of their meanings. Two main principles were followed in coining new terms: that of using the resources of the native tongue, either to give a specialized meaning to an existing word or to form a new one, and that of borrowing a similar term from a foreign language. In defining a new concept, the specialist sometimes employed a word already existing in the language, adding a specialized meaning to its usual one(s). However, the most frequently adopted strategy was the borrowing of terms from other languages, particularly from Latin. Indeed, Latin and Greek were endowed with large and respected specialized lexicons, as too was – although less extensively – Arabic (Standard Arabic). The choice of a loan, rather than the specialization of an existing word or the coinage of a new term, was often suggested by the fact that the concept to be referred to was already expressed in a foreign language. The availability of a term was particularly evident in the case of translation of texts. In that case, when the translator came across a word with no equivalent in the tongue into which he was translating, he was obliged to use the original word, thus enriching the lexical load of the receiving language.

The remarkable increase in the number of new medical terms is in line with the great expansion of the Early Modern English lexicon as a whole (Finkenstaedt *et al.*, 1970), with intense borrowing and neological formations in all fields. The medical sciences seem to reach their peak in the first half of the 17th century, as shown by the numbers of new words provided by Wermser (1976); see Table 1.

However, as they are mainly based on the entries reported in the *Oxford English dictionary* (*OED*), these statistical data should be treated with caution. Indeed, due to the criteria adopted by the compilers,

Table 1 Number of new medical terms

	1510–1524	*1560–1574*	*1610–1624*	*1660–1674*
Medicine, anatomy	12	46	141	84

the data used in compiling this dictionary are incomplete; moreover, many words may have been in use before the dates indicated in the *OED*, either in texts that have not survived into our times or in publications not taken into consideration by the compilers (for a discussion of this issue cf. Schäfer (1980)).

This increase in medical terminology was favored both by the large number of translations from other languages and by original works in English. At the end of many of these works, the authors added a glossary in which they defined some of the new words that they had coined or adopted. This is, for example, the case of the translation by Richard Tomlinson of Renodaeus' *Dispensatory* (1657) to which the publisher adds "A Physical Dictionary. Or, an Interpretation of such crabbed Words and Terms of art, as are derived from the Greek or Latin, in which words such as *abstersive*, *buccellation*, *caliginous*, *cardiogmos*, *circumdated* and *commaculate* are explained." These glossaries – appended to books and explaining 'hard words' excerpted from the texts they accompanied – are the forerunners of the hard word dictionaries (cf. below).

Table 2 Original medical terms and adopted terms created by changes to suffix

	Original term	*Adopted term*
Suffix dropping	*ligamentum*	*ligament*
	empiricus	*empiric*
Suffix substitution	*anatomia/anatomie, zootomia*	*anatomy, zootomy*
	assimilabilis, visibilis	*assimilable, visible*
	deligatio, embrocatio	*deligation, embrocation,*
	imminutio, remollitio	*imminution, remollition*
	narcotique	*narcotyke*
	insalubrité	*insalubrity*
	conflare/conflatus, evaporare/evaporatus,	*conflate, evaporate,*
	lymphatus, ulcerare/ulceratus	*lymphate, ulcerate*
	antidotarius	*antidotary*
	incisorius	*incisory*
	eminentia, indecentia	*eminence, indecency*
Suffix addition	*choler*	*cholerous*
	pinea	*pineal*

Lexical Borrowing

The most frequent policy adopted to increase the English medical lexicon was to take over Greek or Latin terms, sometimes without any change (e.g., *delirium, diabetes, embolus, metacarpion, parenchyma, paresis, pus, uvea, virus*). In the first use of these terms in a text written in English, the authors often added an explanation in vernacular. This is the practice commonly followed by Andrew Borde:

> *Cancer* is the latyn word. In englyshe it is named a canker the whiche is a sore the whiche doth corode & eat the flesshe corruptynge ye Arters the vaynes & the sinewes corodyng or eatynge the bone and doth putryfy & corrupt it. And then it is seldome made whole. (Borde, 1552: 28^{r})

> *Colera* is ye latyn worde. In greke it is named *Cholae*. In englysh it is named Coler, the whiche is one of the .iiii. humours. And it is hote and drye, lyenge or beyng in the stomake and is mouable. There be .v. kyndes of coler. [...] (Borde, 1552: 38^{r})

In general, however, in adopting the loan, the translator usually adapted the word he was borrowing to the morphological features of the receiving language, following the conventions in use concerning word formation. At times, their original termination was dropped (see examples in Table 2), but generally the original suffix was replaced by one commonly used in English. Thus, the suffixes *-s* and *-y* were commonly employed to naturalize foreign nouns referring to scientific branches, *-able* and *-ible* were used to render the Latin adjectival terminations *-abilis* and *-ibilis*, and *-al* and *-ous* were used to form adjectives from foreign nouns, with the suffix *-ous* also being used to adapt adjectives ending in Latin in *-us*. Latin words ending in *-atio*, *-itio*, and *-utio* were provided with the suffixes *-ation*, *-ition*, and *-ution*, the terminations *-ic(k)* and *-ity* were usually employed as adaptations of the French suffixes *-ique* and *-ité*, and *-ate* rendered the Latin endings *-are* and *-atus*; the Latin suffixes *-arius* and *-orius* were usually naturalized in the forms *-ary* and *-ory*, whereas *-ence* and *-ency* were meant as equivalents of the Latin ending *-entia*.

This process of borrowing involved the adoption of not only single words, but also of prefixes and suffixes, which were used more and more often to create new terms. For example, if we consider combining forms of classical origin such as *-ology* and *-meter*, we can see many new English words created in the 17th century including these suffixes, e.g., *pathology*, *ichthyology*, *zoology*, *osteology*, *psychology*, *micrometer*, *thermometer*.

Native and classical elements usually mixed in texts, as can be seen in Copeland's (1541) definition of *ulna*: "The arme is devided in thre great partyes. One is called vlna, the other lytel arme." Indeed, the existing native terms commonly referred to general parts (e.g., *ankle, arm, knee, shoulder, elbow, hip*) and the new terminology (mainly derived from classical sources) defined the component elements of these

general parts (e.g., *ulna, radius, humerus* as components of *arm*). Some native terms experienced a semantic transition from one referent to another, scientifically more appropriate: *womb*, for instance, passed from generalized 'stomach' to exclusively feminine 'uterus.' In some cases, two forms (general and medical) were neo-Latin; in these cases, the former was already present in the language, having been borrowed during the Middle English period, and the latter appeared in the language in the Early Modern English period; some examples of these doublets are *gender / genus, prove / probe, spice / species, palsy / paralysis*. Moreover, once a loan had been introduced, it was frequently used as a root from which further words could be formed by means of affixation. Examples include *parenchyma* > *parenchymatic*, *anatomy* > *anatomical* > *anatomically*. Some neologisms were obtained from existing words (either native or loan words themselves) by means of compounding: e.g., *lung-sick* ('sick of a pulmonary complaint'), *pine-glandule* ('pineal gland').

Although he thinks he is right in borrowing terms from other languages, the writer is aware of the difficulties of interpretation that readers might meet when they encounter the new terms. Therefore, he often tries to help in the form of a synonym when they first appear in the text; typical are cases where the author gives two expressions, a native and a foreign term, elucidating each other ('stones or testicles'). On other occasions, instead of providing a concise synonym or antonym of the new term, the author gives a full paraphrase of it or an exemplification:

> *Androtomy*, as some of the moderns call the dissection of man's body, to distinguish it from zootomy, as they name the dissection of the bodies of other animals. (Boyle, 1772: I. 68)

'Transparent' Terms

Apart from the processes of word formation seen above, the complex operation of creating new terminology sometimes adopted other criteria, based mainly on the pragmatic principle of maximum transparency, which is extremely important in specialized discourse (Gotti, 2003). In the application of this principle, the writer created terms in such a way that their form clearly reflected the concept to which it referred. An example can be taken from Golding (1587), in which the author, in need of new terms, invented transparent forms such as *fleshstrings* for muscles and *primetime* to indicate an early period of world history. These terms may seem so strange as to suggest a desire for idiosyncrasy on the part of the author. Conformity to the criterion of transparency is instead confirmed by Ralph Lever:

> Therfore (gentle reader) if thou doubt, what is ment, by any of our strange and new deuised termes, consider their partes, as they are taken by themselues alone: and the consideration of the partes, shall leade thee to the knowledge of the whole. (Lever *The Arte of Reason, Rightly Termed, Witcraft*, quoted in Jones, 1953: 129)

As we can see, these transparent terms were usually obtained by means of the juxtaposition of words already existing in the English language. This process of compounding was particularly favored by the brevity of English words; in fact, most were monosyllables and could therefore be easily linked to form compounds, which in turn were not too long. However, the recourse to this word-formation process based on native English lexemes was not very frequent, as the decoding of Latinate terms was not a real problem for the medical profession. Moreover, general use would make these new terms common and familiar to the profession as a whole:

> And althoughe perchaunce at the fyrst it may seeme somwhat obscure and harde [. . .] yet yf you doe accustomablye vse to reade them, and conferre either wyth the Apothecarie where as you doe not perfectly vnderstande the same, or elles vse the helpe of a Dictionarie, they wyll bee vnto you bothe familier and playne. (Gale, 1563: Aaaiii^{r})

Glossaries and Dictionaries

Medical terms were already included in dictionaries at an early stage. They constitute a relevant part of the lexemes contained in the 1538 edition of Thomas Elyot's Latin–English dictionary, probably facilitated by the fact that the compiler had studied medicine. Also the reviser of this dictionary, Thomas Cooper, was trained in medicine and dealt with these terms carefully not only in his revision of Elyot's dictionary published in 1548, but also in his own very successful Latin–English dictionary. The standards of these bilingual dictionaries were high and the treatment of medical terms in them was accurate.

The first monolingual dictionaries, instead, presented only a limited and unsystematic selection of medical terms among those that their compilers considered hard words, i.e., semantically obscure and difficult to understand. Indeed, the rapid development in the various scientific branches had caused a dramatic expansion of the English vocabulary and the coining of thousands of new words, which, however, were not always interpreted correctly by readers and were often re-employed wrongly. Therefore, many hard word dictionaries were compiled to present the various Latinate expressions that had appeared so abundantly in English specialized texts

of those centuries, as well as the more obscure words appearing in literary works.

The tradition of hard word dictionaries is generally considered to date back to the beginning of the 17th century. However, even before then, glossaries had been used for the explanation of hard words. In less than a century, these glossaries increased in number and size and gradually developed into separate publications exhibiting great comprehensiveness. It is not at all strange, therefore, that Robert Cawdrey's *Table Alphabeticall* (1604), which is often quoted as the first hard word dictionary, should be published during that period, as his list of hard words could be considered an expansion of those glossaries. Two other very popular hard word dictionaries are John Bullokar's *An English Expositor* (1616) and Henry Cockeram's *English Dictionarie* (1623). (For a survey of monolingual printed glossaries and dictionaries of this period cf. Schäfer (1989) and McConchie (1997).) Some of the medical terms included by Cawdrey are as follows: *adustion, confection*, *debility, entrails, epilepsis, fever, frenzy, fume, genitals, imbecility, judicial, lethargy, obstruction, ministration, ossicle, pest, sperm, tertian, vehement, ventricle*. Also, the following terms belong to the medical field, although the examination of Cawdrey's definitions does not always show a consideration of their medical senses: *antidote, catarrh, decoction, gargarize, flux, instinct, nerve, putrefy, spleen, ulcerate, vapour*. Some of these terms might not sound very innovative for those times, but the fact that they are included in this text means that – although some had been coined even a few centuries before – they had not become very popular among English speakers. These words, however, should only be considered as indicative of the popularity of the terms at that time. Indeed, it should be remembered that the words included in hard word dictionaries were not collected meticulously after a thorough examination of all the specialized texts available; instead, in the selection of his entries, the author mainly borrowed the terms that he thought suitable from the dictionaries and specialized glossaries he had come across in his unsystematic search for appropriate sources for his dictionary.

The picture that can be drawn from a reading of these works is that the medical terminology dealt with in them was involved in a process of rapid growth yet still needed some form of systematization. This impression is backed up by the existence of doublets within the dictionaries to express identical concepts. Indeed, there are often frequent cases in which two different words refer to the same human organ, e.g., *kidnies or reines*. It must be pointed out, however, that the picture offered by hard word dictionaries is more dated than the actual state of medical research at that time, as the author often made use of glossaries and dictionaries published a few decades before. Indeed, if we look at a few terms belonging to the medicine dealt with in hard word dictionaries and coined in the decades preceding their publication, we can see that many of them are not included in those works. Table 3 lists a few terms belonging to the branch of medicine, with the date of their first publication as derived from the *OED* and the *Supplement to the Oxford English dictionary* (*OEDS*); each word is followed by either a plus or a minus sign: the plus sign indicates the presence of that entry in the dictionary mentioned at the top of each column and the minus sign indicates its absence. Table 3 shows the unsystematic approach to the selection of items adopted by the compilers of hard word dictionaries.

A comparison of the distribution of the items in Table 3 shows that Bullokar's interest in medical 'termes of art' was more prominent (Bullokar himself was a physician), as is shown also by the lengthier explanations that accompany the various items:

> *Splene*, milt. (Cawdrey, 1604)
>
> *Splene*. The milte of man or beaste: which is like a long narrow tongue, lying vnder the shorte ribbes on the left side, and hath this office of nature, to purge the liuer of

Table 3 The (non-)Occurrence of some medical terms in the first three hard word dictionaries

Intestine (1597)	–	–	–
Scrotum (1597)	–	–	–

> superfluous melancholicke blood: sometime it signifieth anger or choler. (Bullokar, 1616)

> *Spleene*, The milt of man or beast. (Cockeram, 1626)

In this greater length, we may perceive a tendency toward a transition from mere verbal gloss to an encyclopedic article, which was gradually taking place in several hard word dictionaries, often making the distinction between a monolingual dictionary and an encyclopedia rather unclear. Another interesting feature of Bullokar's dictionary is his inclusion of several terms referring to medicinal plants from the new world, which he had derived from the John Frampton's *Ioyfull Newes out of the Newe Founde Worlde* (1577), a translation of the original book in Spanish by Nicolás Monardes (1574). Such terms are not only reported in Bullokar's dictionary, but they are also given substantial definitions, as shown by this quotation:

> *Sassafras*. A tree of great vertue, which growth in the Florida of the West Indies: the rinde hereof hath a sweet smell like Cinnamome. It comforteth the lyuer, and stomack, and openneth obstructions of the inward parts, being hotte and dry in the second degree. The best of the Tree is the roote, next the boughes, then the body, but the principall goodnesse of all resteth in the ryndes.

The reading of the definitions of some of the entries in Bullokar's dictionary shows that there was still a gap between the specialized terminology of other languages – particularly Latin – and the English tongue; the latter still lacked some of the termes of art that instead already existed in foreign codes. The following quotation provides a confirmation of this state of inferiority; in dealing with a medical term, Bullokar was not able to make exclusive use of English words to express his definition and had to borrow two Latin expressions to refer to the two types of meninges he was describing:

> *Meninges*. Thinne skins in which the braine is contained. There are two such skinnes: one called by Phisitians, *Dura mater*, which is the stronger of the two, and next vnto the scull. The other named *Pia mater*, is within this first, being more tender and fine, and close wrapping the braine it selfe. If any of these skinnes bee wounded, it causeth speedy death.

Syntactic and Textual Developments of Medical English

The 16th and 17th centuries also showed interesting developments in the syntactic features of medical English. Unlike the lexical field, changes took place in a nonexplicit way, as specialists were usually unaware of the syntactic modifications that they were introducing into the language by means of their writings. The new perspective that characterized their research method conflicted with the constraints of the language and forced them to adapt its rules to their expressive needs. Sentences became quite long, with very lengthy noun phrases preceding and following the verb. Moreover, the verb (often represented by forms of *to be*, often accompanied by present participles) started assuming the copular function usual in modern scientific English, where the verb merely links the very long nominal phrases coming before and after it. Each sentence was structurally simple, with few or no subordinate clauses, complying with the modern preference for coordination rather than subordination in sentence structure. Moreover, there was a large number of words referring to processes and a distinct preference for the use of nouns deriving from verbs. This linguistic preference, which is commonly referred to by the term 'grammatical metaphor' within Systemic Functional Linguistics (cf. Halliday, 1994), has become one of the salient features of scientific discourse and can be explained by the fact that verb-derived nouns reflect the parallel process whereby results are inferred from experiments and objects from their construction process (cf. Halliday and Martin, 1993). An example of this preference can be seen in the use of processes such as *inspection* and *dissection* in the following definition drawn from the manuscripts of William Harvey's lectures delivered at the Royal College of Physicians in London around 1616:

> Anatomy is that faculty which through inspection and dissection reveals the uses and actions of the parts. (Harvey, c. 1616: 22)

Indeed, the adoption of nominalized forms was becoming more and more popular as, by allowing the thematization of the actions commonly expressed by verbs and increasing the textual potentialities of those lexemes, it enabled the scientist to include more information in the same sentence and guaranteed a better flow of his discourse. Another advantage offered by the process of nominalization consists of allowing the writer to create concise noun phrases, which can be made to perform the various different syntactical functions required in specialized texts. The increase in the use of nominalization was part of a gradual tendency toward a loss of importance of the verb, compensated by a growth in importance of the noun. This change was mainly for textual reasons, as the process of nominalization promoted a better cohesion of the text by means of the recovery of the information given in the previous statement as the theme of the following sentence.

Also from the textual point of view, there is a great development in this period; the early printed works mainly consist of translations of treatises and new compositions of general guides to health and handbooks of medical instructions, often including accounts of illustrative and typical cases (Bennett, 1969). The normal mode of publication for scientific work was in a separate treatise and men of science kept abreast of the times through private manuscript correspondence. The 17th century shows a greater variety of genres, with the addition of new forms such as anatomical observations, book reviews, journal articles (Lefanu, 1937), and experimental essays (Gotti, 2000). The first English medical periodical was the *Medicina Curiosa*, of which the only two numbers extant appeared on June 17, 1684 and October 23, 1684, as part of a wide phenomenon taking place all over Europe (Garrison, 1934). After the formation of scientific societies (Rome, 1603; Paris, 1635; London, 1660; etc.), the serial publication of their *Acta* developed (cf. the issues of the *Philosophical Transactions of the Royal Society*).

The experimental essay originated in the Early Modern English period as a result of a complex process of scientific evolution, which determined the need for a new expository genre to suit the new epistemic approach of 17th century 'natural philosophers.' The innovative characteristics of this new text type derived from the great importance attributed to the experimental process in the research programs of Early Modern English men of science, who – elaborating on Francis Bacon's intuitions – shared the principle that the progress of knowledge could not be based on the servile observance of traditional theory, but should rely on the observation of natural phenomena and accurate experimental activity. Hence, there was a need for a form of expression that would offer the scientist the opportunity to report briefly experiments carried out, procedures followed, results obtained, and any personal comments. This genre was identified in the experimental essay, which became very popular also in the medical field. To appreciate the importance of the latter genre, we should consider the fact that, in the following centuries, whereas some forms of specialized writings – such as the dialogue – almost disappeared, the experimental essay survived and became an essential part of specialized literature, as the rapid diffusion of scientific journals made it an established genre commonly used by men of science. Although most of the structural parts of this textual genre originate from Early Modern English experimental essays, early essays showed more frequent use of the active form, the report of unsuccessful experiments, and less emphasis on theoretical conclusions than nowadays. Moreover, they were characterized by first-person narration, subjective point of view, and expressions of low modality (Taavitsainen, 2001).

Medical Discourse: Doctor–Patient Communication

R Wodak, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A number of new developments in the research on doctor–patient communication are discussed in this paper. First, I provide a brief overview of the most important theoretical and methodological paradigms in this field. Then, I provide some examples, based *inter alia* on a qualitative empirical study in an outpatients' clinic (Lalouschek *et al.*, 1990), as well as on innovative and recent research on the expression of pain (Vodopiutz *et al.*, 2002). As doctor–patient communication takes place in different institutional settings, such as hospitals or private clinics, I also consider some features of the rules and norms governing institutional discourses (Wodak, 1996; Iedema, 2003; Sarangi and Roberts, 1999). Moreover, it is of particular importance to evaluate new work that utilizes virtual communication, in other words, the Internet. The impact of this kind of research on the medical profession and possible application of research results will also be of interest.

Doctor–Patient Communication

Communication in institutions is a major area of investigation in sociolinguistics and discourse analysis. In the domain of 'critical linguistics' (Wodak and Meyer, 2001), communicative interactions in relevant social fields need to be made transparent. Institutions incorporate such areas and manifest social structures, power allocations, hierarchies, and access to positions and information, and they define societies in their subdivisions of work. Institutions have their own value systems, which crystallize in ideologies unique to particular institutions (Mumby, 1988). It is important to make a distinction between claims and expectations explicitly uttered in accordance with a professional ideology (such as *the doctor is there for all patients in equal terms*) and implicit, latent norms and rules (such as *publications and empirical studies are more important for a clinical career than healing patients*). The contradictions in practice that arise from such norms are often concealed and legitimized with myths, in the sense of Roland Barthes (1974). 'Myth' is understood to mean a secondary semiotic system that constitutes, as it were, a second layer of reality that all participants (are obliged to) believe.

At the same time, there is an important applied aspect to institutional research that is relevant to practice: analyses of the status quo have made it possible to develop proposals for changes in communication, for example, in training programs for members of institutions or for a different approach on the part of clients (Azoulay *et al.*, 2000; Kurtz *et al.*, 1998). Sociolinguistic analysis has therefore proved to be an essential part of the investigation of institutions, since a purely sociological analysis is not capable of making transparent the details of dynamics and processes and is therefore obliged to adopt a high level of abstraction (Weick, 1985). The above-mentioned studies, carried out by medical researchers, are mostly quantitative and use content analysis or measurements of information acquired through questionnaires and interviews; these tools, however, mostly allow for self-assessment and are often oriented toward the investigators who might

Medical Discourse: Doctor–Patient Communication

R Wodak, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A number of new developments in the research on doctor–patient communication are discussed in this paper. First, I provide a brief overview of the most important theoretical and methodological paradigms in this field. Then, I provide some examples, based *inter alia* on a qualitative empirical study in an outpatients' clinic (Lalouschek *et al.*, 1990), as well as on innovative and recent research on the expression of pain (Vodopiutz *et al.*, 2002). As doctor–patient communication takes place in different institutional settings, such as hospitals or private clinics, I also consider some features of the rules and norms governing institutional discourses (Wodak, 1996; Iedema, 2003; Sarangi and Roberts, 1999). Moreover, it is of particular importance to evaluate new work that utilizes virtual communication, in other words, the Internet. The impact of this kind of research on the medical profession and possible application of research results will also be of interest.

Doctor–Patient Communication

Communication in institutions is a major area of investigation in sociolinguistics and discourse analysis. In the domain of 'critical linguistics' (Wodak and Meyer, 2001), communicative interactions in relevant social fields need to be made transparent. Institutions incorporate such areas and manifest social structures, power allocations, hierarchies, and access to positions and information, and they define societies in their subdivisions of work. Institutions have their own value systems, which crystallize in ideologies unique to particular institutions (Mumby, 1988). It is important to make a distinction between claims and expectations explicitly uttered in accordance with a professional ideology (such as *the doctor is there for all patients in equal terms*) and implicit, latent norms and rules (such as *publications and empirical studies are more important for a clinical career than healing patients*). The contradictions in practice that arise from such norms are often concealed and legitimized with myths, in the sense of Roland Barthes (1974). 'Myth' is understood to mean a secondary semiotic system that constitutes, as it were, a second layer of reality that all participants (are obliged to) believe.

At the same time, there is an important applied aspect to institutional research that is relevant to practice: analyses of the status quo have made it possible to develop proposals for changes in communication, for example, in training programs for members of institutions or for a different approach on the part of clients (Azoulay *et al.*, 2000; Kurtz *et al.*, 1998). Sociolinguistic analysis has therefore proved to be an essential part of the investigation of institutions, since a purely sociological analysis is not capable of making transparent the details of dynamics and processes and is therefore obliged to adopt a high level of abstraction (Weick, 1985). The above-mentioned studies, carried out by medical researchers, are mostly quantitative and use content analysis or measurements of information acquired through questionnaires and interviews; these tools, however, mostly allow for self-assessment and are often oriented toward the investigators who might

be seen as authorities. Yet the detailed microanalysis of conversations between doctors and patients in various settings provides more authentic insight into on-going interactions, misunderstandings, satisfactions, and dissatisfactions as well as insight into compliance. Nevertheless, a textbook, such as that by Kurtz *et al.* (1998), is most certainly to be viewed as a first important step to be complemented by sociolinguistic and discourse analytic proposals (Lalouschek, 2004). Thus, the discourse analytical approach has made it possible to uncover the workings of explicit and latent institutional rules and norms in every specific text and to demonstrate how power structures, gender relations, etc. are always manifest and constantly (re)-produced in interaction.

To summarize briefly the most important sociolinguistic research on institutions, we find the following picture, which indicates tendencies but does not permit simple generalizations:

- Institutions are anonymous: the names of clients, for example, are known, but the names of insiders often remain secret. Written products, such as forms, rulings, and legal texts, are mostly written in the passive voice and characterized by vagueness.
- Institutions have their own specific rituals: in many institutions historically determined linguistic forms (such as forms of address, greetings, and oaths of loyalty) that have lost their specific function have developed. These also include dress regulations, rites of initiation, etc.
- Institutions have a quasi-military character: power and hierarchy are essential components of the internal dynamic. Many linguistic actions might take on the explicit character of requirements, requests, or even commands.
- Institutions strive to reflect harmony: contradictions and conflicts are often concealed and not discussed or exposed openly; this might lead to many latent tensions that affect the interaction with colleagues or with patients in the wards.
- Institutions are usually status oriented: members of the upper classes are often treated quicker and more thoroughly than others, men better than women, nationals better than foreigners or migrants (always depending on the country of origin), and more experienced patients more efficiently than the inexperienced. Social class, gender, education, ethnicity, and so on combine in unique ways and play an important role how individuals are perceived and treated by an institution. Typically, the most important positions are occupied by powerful, white males.
- Institutions often work inefficiently: inexperienced specialists frequently occupy the most important interfaces with the general public, such as in the outpatients' clinic or in the reception area of hospitals. This means that often no decisions can be taken and problems must be referred to other experienced doctors or nurses (Coiera and Tombs, 1998). Moreover, experienced insiders in subordinate positions (such as nurses) sometimes must present their knowledge with great care so as not to constitute a threat to the more powerful specialists.

A Short Overview of Research

Research on doctor–patient communication relies mainly on two approaches: the medical–sociological approach, which is oriented toward the institutional structures, and linguistic research, which focuses on microstructural aspects of communication and interaction. Thus far, there has been little success in unifying these two aspects.

For example, Cicourel (1981), using a number of case histories, already showed the advantage of a conversation-analytical procedure as opposed to quantitative psychological categorizations. He cautions repeatedly that the structural framework must be included together with the different perspectives of the two principal protagonists – the doctor and the patient (doctors want to reach a diagnosis as swiftly as possible, whereas patients want to tell the story of their suffering; this results in conflicts of both time and interest that are sometimes difficult to resolve: 'frame conflicts') (*see* **Medical Specialty Encounters**).

In the United States and United Kingdom, research focused more and more on the analysis of individual conversation patterns, such as question–answer sequences and other adjacency pairs. Since these are often isolated from the context of the complete ongoing discourse, they may ultimately be interpreted only to a limited extent (Fisher and Groce, 1990; West, 1990; Todd, 1983). Nevertheless, relevant insights from such research, albeit from 20 years ago, must be mentioned at this point: Todd (1983) described the collision between the institutional and lay worlds as a 'frame conflict': value systems, modes of knowledge structuring, and handed-down experiences diverge. The structural result of this kind of interaction is repeated misunderstanding and conflict. Mishler (1984) has shown that research remains in "the voice of medicine" and that scientific interpretation is therefore accomplished from the viewpoint of experts, but the signals from patients are ignored. Cordella (2004) has also illustrated in her empirical

study that the 'voices' of patients are often ignored. (*see* **Doctors and Patients in Multilingual Settings**).

Erickson (1999) has carried out a particularly thorough and detailed investigation of the roles and identity conflicts of doctors that give great insight into difficult decision-making situations. Specifically, the combination of training young doctors and treating patients at the same time leads to situations of conflicting interests (see also Menz, 1991).

In German-speaking countries, research was originally dominated by medical sociology, which lacked a linguistic toolkit. The center of interest was case histories and conversations during doctors' ward visits. Bliesener's work (1982), however, on conversations during ward visits was certainly the first relevant attempt to capture a particular substructure of everyday life in a hospital from a discourse analytical viewpoint. Visits are broken down precisely into their features and phases, and the obstacles to successful patient communication are demonstrated in detail. However, the genuinely sociolinguistic aspect was overlooked: whether, for instance, women and men, old and young patients, are treated differently. Bliesener's claim is that simply devoting more time to patients does not solve the problems of obstacles to doctor–patient communication. The quality of the conversation would have to be significantly changed to permit alternative types of communication to develop.

In addition, Hein (1985) – in a then innovative pilot study on family doctors – was able to illustrate the presence of class-specific language barriers in communication with patients of different social backgrounds. The same family doctors prescribed for lower class patients suffering from sleep disorders psycho-pharmaceuticals, whereas for middle-class patients (with the same symptoms) they recommended psychotherapy, valerian drops, or autogenic training. In the first case, the doctor–patient conversation was typically short, full of closed questions, and often cynically derogatory, whereas in the second case, the conversations were twice as long, amicable, and full of anecdotes and digressions (Hein and Wodak, 1987) (*see* **Medical Discourse: Illness Narratives**). Lalouschek (1995) analyzed, in a longitudinal study, the training of psychosomatic specialists. Here, too, she found that because of a lack of self-reflection on the part of the doctor, little success was achieved. The change to a rather more therapeutic mode of conversational behavior was rarely made or made in an exaggerated fashion. Her conclusion was as follows: training must become considerably broader and more complex, and above all the results of discourse analytical research should be included. Even in these studies, however, the definition of the unit of discourse was isolated and limited. The everyday life of the institution was only partially considered. New research has now developed the more holistic approach further with the aim of applying linguistic research in training seminars for doctors (Becker-Mrotzek and Brünner, 2004).

Sociolinguistic and Ethnographic Studies: Pain, Fear, and the Everyday Life of the Hospital

All of the studies thus far mentioned with few exceptions derived from an external perspective; i.e., certain discourses were arbitrarily extracted from the life of the hospital and analyzed according to prior assumptions. The relationship to the institution and to the life of the institution is essentially lost in such a process. Because of this limited knowledge of the context, the interpretations have only little validity.

In an investigation of the outpatients' ward of a hospital in Vienna, it was the internal perspective that we were concerned with (i.e., the perspective from the viewpoint of the participants): we set out to observe, understand, and record mornings as a closed discourse unit and to then conduct conversations with both doctors and patients before and after this time (Lalouschek *et al.*, 1990). We shared, as it were, the life of this clinic for a certain time. Because of this participant observation, it was possible to discover – alongside the familiar static social variables – some meaningful new dynamic categories. The outpatients' clinic itself was perceived as an outpost – a "penal colony" in the words of one doctor – of low prestige and therefore a job for doctors in training. This means, as mentioned above, that at the most important interface with the outside world, inexperienced insiders are located instead of experienced ones. This leads to chain reactions: inexperienced doctors cannot make decisions and so senior doctors must be summoned. People must wait for them and this wastes valuable time. As a stereotypical answer to our questions, we learned that doctors have too little time and never make mistakes and that there is simply no better way. And in the everyday world, strategies had to be developed on the spot to cope individually with any problems that arose.

The discourse analysis always related to an entire morning (as a macrodiscourse); every individual conversation constituted a subdiscourse that should always be seen within the total context of the setting in the hospital and the specific morning. In what follows, I focus on a few categories used in analyzing some sample conversations between doctors, patients, and nurses.

The *occurrence of patient initiatives* (questions for information, stories, complaints, judgments) and the doctors' way of dealing with initiatives (answers, interruptions, cutting off, ignoring, and so on) demonstrate forms of exercising power on the part of the doctors as well as the voices of the patients. The quality of a frame conflict can also be captured in this way.

Every specific *discursive coping with problems* by the doctors demonstrates the assumed contradiction between explicit rules, myths, and actual events. (If doctors become aware of problems, do they deal with them or defer them? Do they turn the associated uncertainty and aggression against others? In particular, how do doctors deal with problems that are perceived by patients?)

The specific *creation of a relationship* involves basic factors in relationship management. If it proves possible to create a personal relationship, perhaps by means of 'social turns', if important politeness rituals are observed, if particular forms of address employed, and so on, does this lead to more compliance (Wodak, 1986)?

A Typical Morning

On this particular morning, a male doctor and a female doctor are working together. Both are overtired; both have been on night duty. At 9:45, the second patient enters. She is considered to be a difficult patient, because of her age (87).

1 DF2: Right we'll have to take off the gown too
P: (. . .) don't
2 DF2: Why not? – We are in the hospital you know. Right –
3 DF2: now then let's sit down her shall we?
P: /quietly/ (. . .)
4 DF2: RIGHT take off the gown please.
P: [Gown – but I've
5 DF2: [Take it off please – the gown. We've
P: got nothing under the gown.
6 DF2: got to do an ECG. Right No one's
P: (. . .) Gown
7 DF2: looking – well – it's only the doctor
8 DF2: – isn't it. He's allowed
P: [The doctor can look – but
9 DF2: to look isn't he – right let's sit down here
10 DF2: shall we. exactly
P: [Sometimes he even has to look (. . .)
11 DF2: Right – tell me, which was the broken arm?

64 DF2: She keeps wobbling around – NOW JUST LIE STILL
65 DF2: DON'T KEEP WOBBLING AROUND – OR THE ECG WON'T WORK
66 DF2: QUITE STILL – JUST RELAX OK. Good – right:
P: [All right – yes.
67 DF2: that's fine.

221 DF2: But she's sore EVERYWHERE – she's sore
222 DF2: everywhere. DOES IT HURT THERE TOO?
P: Ah: yes / sighs / (. . .)
223 DF2: Ah, not there – only the back and there it hurts,
P: [it's OK
224 DF2: right? Yes – and there?
P: It hurts there. [Well – I can feel it but
225 DF2: [not too bad.
P: it's bearable.

First, the patient is asked to take off her blouse; she is then examined; and only then comes the first question: "what problems have you had, then, with your heart?" Next we hear the patient's own account: she got herself worked up. "Old patients shouldn't get themselves worked up," says the female doctor, raising the matter of age for the first time. The social turn then comes to an abrupt end ("all right"), and there follows a closed question: "whereabouts in your stomach does it hurt?" Finally, toward the end, the patient seems cooperative. What is striking about this macrostructure is that instead of the usual questioning activities at the beginning, there are initially speech acts of demands and the consultation sequence is embedded into these.

When the patient does not want to take off her blouse, after a first indirect speech act, linked to a childish form of address such as "we have to," there is an unsatisfactory explanation. This form of address – *pluralis hospitalis* – is often employed with old people. After a structuring signal ("right"), the female doctor makes a second attempt: ("right, would you take off your blouse, please"): this is more polite but also direct, with the unmistakable character of a request (almost as command), using the more distant form of second-person address and a sociophonological switch to standard pronunciation: "take it off, please, your blouse." Finally, there is a simple explanation. The patient still quietly resists, and the next explanation follows: only the (male) doctor is there, and the particle "OK" serves as a closing signal and as reassurance. "He can look," says the patient, half-questioning, half-submitting. This is repeated by the female doctor, and again a closer relationship develops expressed in dialect and the word "OK," to which is attached a further appeal and a concluding and reassuring "OK." The old woman repeats: "he has to look sometimes," as though she was trying to convince herself. "Exactly," replies the female doctor in confirmation; she changes the subject, again with a structuring "so," and the examination begins with the first closed questioning activity. This is realized as a

further command (the fourth command in this short text) in which impatience is clearly manifest. In the following part, the female doctor yells at her, no longer able to control her annoyance, and the seventh direct request is realized in standard language. This is immediately followed by four more direct requests. For this, she later expresses regret. The closing section of the conversation is polite and calm; we find the third form of address: they are talking about the patient ("everything hurts her"). This causes a great deal of uncertainty in patients, since it is not clear who is being referred to. Only the change to quite direct questioning and a different form of address makes this switch clear: the utterance was aimed at the other doctor. The patient is now well behaved. She has adapted to the institutional frame.

The female doctor therefore oscillates, in her handling of the patient, between coming close, impatient distancing behavior, and brutal authority. This communicative behavior is, on the one hand, a kind of power display, but on the other hand it reflects her state of conflict that may be attributed to a number of factors: it was her first consultation in the presence of a tape recorder; the patient was also 'difficult,' since she is very inexperienced and causes a delay in the sequence of events. This case is therefore perceived as a disturbance, as uncooperative behavior, and the doctor does not succeed in reducing the patient's fear and establishing a reasonable relationship and trust. Explanations and information are denied precisely where they would be needed. In the end, the patient becomes completely silent. Here frame conflict and language barriers are obstacles to face-to-face communication. In the outpatients' ward, the staff is not equipped for this kind of disturbance. The examination lasted 21min.

The Rest of the Morning

After 11:00 A.M., there was a loudspeaker announcement: "Attention please: here is an announcement. The Götzendorf field ambulance will be assisting in snow clearance in the car park from 1:00 P.M. onward. All staff are requested to remove their cars to make this work easier."

Initially the content of this announcement causes laughter: "Oh God, they can't be serious. One o'clock this afternoon. We'll never get out. That'll be fun…" When the doctor gradually realizes, however, what the announcement means, she becomes menacing: "But look, but there's the training at 1 o'clock, I haven't – I think it's 3 weeks since I last went for training…Where can I put it? We'll just leave it. I can't cope any more." The doctor transfers this bad mood to the waiting patients: "They're still there waiting. How many more are there, you hear me?"

The strain apparently can no longer be tolerated, and any reasonable way of handling the situation is prevented. Here it becomes particularly clear how important it is to have a precise definition of a discourse unit and the context. Taken out of context and treated as a single sequence for investigation, the doctor's behavior could only be interpreted as uncontrolled and irrational and, in general, as unwillingness to become involved with patients. In the total context of the morning, in contrast to the first consultations, this discursive phase takes on a different value, as an example of an inability to deal with conflict and a lack of problem-solving strategies (Van Dijk, 2003; Panagl and Wodak, 2004). For this reason, the final phase of the morning becomes hectic and full of tensions, the case consultations become significantly shorter, and postconsultation discussions are completely missing. Initiatives are no longer responded to and distance is indicated.

Dealing with Pain: Gender-Specific Differences

Chest pains are a frequent cause of admission to hospitals, and they can be caused by a number of different conditions, ranging from a harmless pulled muscle to life-threatening coronary heart disease (Everts *et al.*, 1996). Despite highly developed technology in the diagnosing of coronary diseases, there remain a number of uncertainties that complicate a diagnosis. Apart from the findings of such diagnostic tools as ECG and chest X-rays, together with laboratory investigation, consultation with a patient still plays a significant role in a diagnosis. In determining the cause of chest pain, the patient's description of the pain is most relevant (*see* **Medical Discourse: Communication Skills and Terminally Ill Patients**).

Medical investigations have shown that in women a dangerous coronary condition requiring treatment more frequently goes unrecognized, and instead an erroneous diagnosis of some harmless noncoronary cause is made. A number of medical studies have shown that these differences may be traced back to different descriptions of pain (Penque *et al.*, 1998). For this reason, on the medical side, an interdisciplinary project was initiated at the interface between cardiology and discourse analysis. In this project, one of the guiding hypotheses was provided by the clinical experience: coronary conditions are more difficult to diagnose in women. Thus, are there gender-specific forms and linguistic behaviors in the description of pain?

Out of a complete corpus of 102 recorded interviews developed to elicit the most spontaneous and comprehensive descriptions of pain, a total of 24 interviews were selected according to criteria of gender, cause of illness, and age, and these were subjected to a discourse analytical investigation. Like other previous investigations, this study showed that in doctor–patient communication, gender-specific differences become salient. The linguistic differences in the description of chest pain that were discovered in the present discourse analytical investigation may possibly contribute to the fact that coronary problems are more frequently overlooked in female patients than in males and that consequently the mortality rate is higher (Vodopiutz *et al.*, 2002).

Differences were found in four different areas in particular:

- Women downgrade their pain (diminish it or talk instead about the psychosocial environment); men rate their pain highly (take it seriously, show themselves as informed and interested).
- Women regard themselves interactively as tolerant of pain (passive with respect to the pain and delegating the treatment to the institution 'hospital'); men present themselves in the interaction as dealing with their pain (active with respect to the therapy).
- Men display more strongly than women a desire for explanation of causes.
- Men describe their pains very concretely (in the sense of the definition), in that they give very full symptomatic descriptions; women, conversely, give diffuse descriptions of pain (in the sense of the definition), in that they barely focus on symptomatic aspects and frequently use markers of diffuseness and meta-communicative utterances, in which they talk of the impossibility of describing their pains precisely.

Strikingly, no age-specific differences were found. These differences have relevant implications in doctor–patient communication because the linguistic activity of men fulfills the expectations of the medical staff to a much greater extent than that of women with regard to the desired information, for doctors both need and require a symptomatic description of pain – that is, the most exact possible statement of location, intensity, and duration or frequency of the incidence of chest pain. The result of this is that patients who spontaneously pursue what they see as the relevant 'clarification of causes' and give predominantly symptomatic descriptions of pain are viewed by the doctors as more precise, informative, and cooperative. Since the major proportion of cardiologists are still men and the description of symptoms and the clinical differential diagnosis of coronary heart disease were developed predominantly with male patients, this bias is possibly inherent in the system.

Final Remarks: Information for the Informed!

Let us sum up briefly: the division between the beginning and the end of the morning in the outpatients' clinic is also manifest in the degree of emotionality. Ultimately, 'difficult' patients are accused of causing the disturbances, and so the scapegoat is outside the outpatients' clinic rather than anchored in the structure. The clients are made into an external enemy; the institution defends itself and functionalizes its contradictions both consciously and subconsciously. Only a precise context analysis, an understanding of everyday life in the institution, and a sequential analysis of the discourse make it possible to grasp what is happening, to reveal the contradictions and the use of power. Since what is not permitted is not done, myths and rationalizations are preserved, which often puts a stop to any reflection or possible change. In the second case, it becomes clear again how important the category of gender is in communication and how relevant the conscious perception, admission, and sharing of pain are. Not only must medical education give training in conversational competence, it must also include knowledge of emotions and the different socialization patterns of the two genders.

Can a face-to-face conversation with a doctor be replaced with the use of new media, such as websites, debate forums, or the Internet? Could this help overcome staff shortages? On the basis of research on Internet communication and on the websites of individual doctors and group practices, this kind of claim must be seen as unrealistic (Danet, 2001; Herring, 2001). The Internet can be sensibly used only by those who know precisely what they are looking for. Initial barriers affect both expert knowledge and language. Medical experience is also essential, because one must be able to distinguish between commonplace advice and detailed suggestions. If one is really looking for precise help, one inevitably comes up against specialized knowledge, scientific articles, mostly in English, on individual medical problems. How can a lay person deal with this? And how can one assess whether particular diagnoses and therapies are applicable to one? A real face-to-face interaction and conversation with a doctor therefore remain indispensable. On the other hand, the Internet or some other multimodal channel functioning as advisor may sometimes be helpful in finding important starting points or in giving patients the feeling that others have similar problems and thereby reducing fear

and shame. Alternatively, after an established diagnosis, it enables chatroom conversations with other 'fellow sufferers,' and this helps to reduce loneliness and fear. A precondition, however, must still be a conversation – not 'virtual' – but face to face, because the problems of each patient remain unique and must be seen in the context of the patient's everyday life. This will always require empathy, listening, and questioning skills as well as sufficient time to follow and understand the sometimes too brief or maybe too extended narratives of the patients, thus detecting the relevant points to come to an adequate diagnosis.

Medical Discourse: Early Genres, 14th and 15th Centuries

I Taavitsainen, University of Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Western science was initiated by Greek philosophers, mathematicians, and medical persons in their search for principles of nature, including human nature, and of argument itself (Crombie, 1995: 225). Knowledge disseminated into Latin via Arabic and from Latin to western vernaculars. Latin prevailed as the language of learning in Europe until the 18th century and served as the *lingua franca* of science until much later. In the late medieval period, scientific and medical ideas were expressed mainly in Latin, but texts started to be translated into various vernaculars and the circle of learning widened. The discourse world of medicine was multilingual: Greco-Roman texts provided the model for vernacular treatises and the standard against which the evolution of vernacular scientific writing can be projected. The influence of the Latin models on vernacular languages, and on the development of vernacular genres, has often been underestimated.

Medical Discourse and the Languages of Writing

In modern linguistics, 'medical discourse' refers collectively to the communicative practices of the medical profession, both written and spoken. In the late medieval period, the medical profession consisted of heterogeneous groups of practitioners, including physicians, surgeons, barbers, midwives, itinerant specialists (e.g., bonesetters and oculists), herbalists, apothecaries, wisewomen, and others. They can be roughly divided into clerical and elite practitioners and tradespeople or ordinary practitioners; literacy was restricted mostly to the elite group. The core genres of learned Latin writing were used by a small elite of learned physicians and surgeons, and included commentaries, *compilationes* ('compilations') and encyclopedic treatises, question-and-answer guides, pedagogical dialogues, *consilia*, and *practica*; some treatises are called 'sermons,' but without further specification of the term. The Latin situation provides a starting point for the assessment of vernacular genres, although the users of vernacular texts and the genre map are somewhat different.

Readership of Vernacular Texts

Genres are important operational tools and constitute dynamic systems that undergo change and variation. Over the course of time, sociocultural needs change and genres change accordingly: old genres become adapted to new functions, new genres are created, and genres that have lost their function cease to exist. The question of audience is important. In earlier literature, language and audience were thought to correlate, so that Latin was associated with learned writing for professionals and vernacular languages were linked with more popular texts for lay audiences. Recent research has proved that this distinction does not hold, but the pattern is more complicated. For example, surviving evidence indicates that the readership of texts addressed to 'the poor' and 'unlearned' in prologues and dedications is not to be taken at face value. The real consumers can be assessed through external evidence, such as library catalogues, wills, and ownership inscriptions. According to this evidence, owners and potential readers were mostly people of high rank in society and professionals in the field of medicine. For example, French-language copies of the popular verse encyclopedia *Sidrak and Bokkus* were owned by important figures in English political life, including Simon Burley, tutor to Richard II (Burton, 1998: 1:xxxiii). Guy de Chauliac's surgical writings constitute highly learned compilations, and these texts were also translated into vernacular languages. Their distribution shows how learned knowledge disseminated throughout Europe. The Latin originals (c. 1360) were targeted at doctors of three leading faculties of medicine, Montpellier, Bologna, and Paris, and doctors and clerks of the papal court (McVaugh, 1997); thirty-three Latin manuscripts are extant. In the 15th century, Chauliac's works were translated into several vernaculars, with at least three anonymous translations in Middle English. The audiences of the vernacular versions must have been more heterogeneous, but conclusive evidence is lacking. Some of the manuscripts show no signs of wear or use at all. Rather, they seem to have been display objects, with the vernacular serving in a new function in the prestige register of scientific writing.

Transfer of Latin Genres into Vernacular Languages

In the late medieval period, there was a gradual increase in vernacular writing in various realms of knowledge, so that by the 14th and 15th centuries, texts dealing with scientific, medical, and technological subjects were becoming increasingly common in Europe (Crossgrove, 1998). By the end of the 14th century, conventionalized discourse forms had been created to present and organise knowledge in Latin; they can well be called 'genres,' as genres are defined according to the functions that they fulfil in society. Genres of Latin writing had become legitimate modes

for disseminating learning, but they developed and changed during the period in question. New writing forms and genres like *consilia* and *practica* were created, new diseases were treated, and new fields, such as astrological physic and medicinal alchemy, emerged. The process of vernacularization started in the 14th century and took place on a broad front in the multilingual context of medieval Europe in several countries roughly simultaneously. The register was new in these languages, and the means to express scientific ideas did not exist; they had to be created. Vernacular texts occupied an intermediate position between the world of learning and the more popular attitudes, between *ars* and *vulgus,* as demonstrated by the German versions of Bernard of Gordon's *Lilium medicine* (original 1305), which was also translated into Middle English, French, Castilian, Gaelic, and Hebrew (Demaitre, 1998: 88). Genre conventions of scientific writing in English writing show a great deal of fluctuation; features of vernacularization are likely to be parallel in different languages.

Traditions of Vernacular Writing

Some genres survive in written vernaculars even from earlier periods, e.g., handbooks with practical advice, recipes, prognostications, and charms are extant from late Old English. We can talk about different traditions of writing, defined as a continuing series of texts building on one another, with a great deal of intertextuality. The traditions are an underlying factor, with several genres within them. Learned translations of academic and surgical texts were new and emerged in the last quarter of the 14th century, whereas the remedy book tradition is longer and goes back to the 10th and 11th centuries in English (Voigts, 1984). Yet the aforementioned division into three traditions is not always clear. Surgical texts are easy to identify because of their subject matter, but academic writing is a difficult category because of the lack of knowledge of early authors and their audiences. Likewise, remedy books are a difficult category, as these texts also contain learned materials, which may have come to vernaculars earlier, and there are several chronological layers of influence and borrowing.

Institutional Settings of Medical Discourse

Medicine as a Discipline

The position of medicine among sciences is special because of the relationship between theory and practice; this problem occupied learned writers for centuries. Medicine was both a learned university discipline and an occupation involving technical skills. Medical education comprised both general theories and specialist doctrines, but also practical applications through apprenticeship. The development of learned genres from the 12th century onward took place within an institutional context, with the newly founded universities as centers of medical learning (Crisciani, 2000: 75–78). More practical, non-institutional writings are extant in great numbers in both Latin and in vernacular languages.

Institutionalization of Medical Education

Before the founding of universities, medicine was taught in households of noble patrons or in medical schools attached to monasteries or cathedrals. From the 11th century onward, the Latin western world began to seek out a fuller version of ancient wisdom. Italy was in the forefront of the developments in the formation of writing conventions and establishing textual traditions, with new institutions and expanding scientific horizons. The 12th century has come to be seen as the starting point for a long medical Renaissance, because intellectual traditions that, evolving over 400 years, eventually began to resolve a broad range of issues, thereby defining a new science of medicine, which grew out of a range of equally new areas of scholarly investigation (McVaugh and Siraisi, 1990: 9). The influence of the new translations from Arabic in natural philosophy and medicine started in the 12th century, e.g., Constantinian translations date from this period. The center of medical knowledge was Salerno, Italy, and the most important product of the school of Salerno was the fully developed textbook known as the *Articella*, a collection of classical medical knowledge with Arab learning (French, 2003: 72; Ottosson, 1984: 60). Universities became institutionalized in the 13th century, and there was a general agreement about the form and content of medical teaching throughout Europe. Oxford and Cambridge, like others, were monolingual in Latin and part of the pan-European educational network that paid no regard to the vernacular. Institutional developments promoted the creation of discourse forms in a more formalized direction.

During the 14th and 15th centuries, the growth of towns in Europe was rapid, and various kinds of corporations started to develop. Teachers of medicine formed masters' guilds and taught their pupils to a level of 'master,' thus controlling the continuity of the trade (French, 2003: 70). An important step toward the institutionalization and full development of medical training took place in England, with the establishment of the guilds of practicing barbers and surgeons in the late 14th century. Guilds started to record their official documents in the vernacular;

for example, the Barber-Surgeons of York gathered all kinds of useful information into their guild book from the year 1486 in English and Latin. It is likely that the medical treatises in this book were used in instruction, but otherwise, vernacular medical literature was probably non-institutional.

Latin Genres of Learning

Commentaries and Compilations

'Commentaries' and 'compilations' (*compilationes)* were at the heart of the intellectual mainstream of scholasticism. According to medieval literary theory, commentaries are distinguished from compilations by the fact that the commentator takes the responsibility for conclusions. His own materials are "annexed for the purpose of clarifying" the issues, whereas opinions are attributed to others by the compiler, who "writes the materials of others, adding but nothing of his own" (Minnis, 1979: 387; quotations from Bonaventura translated by Minnis).

Commentaries were used both for research in reconciling ancient authorities and in teaching. The twofold nature of medicine shows in them, as, in addition to the truth and meaning of the work, the commentator had to point out its usefulness (Crisciani, 2000: 79). Each discipline had a canon of authoritative texts. The commentary tradition has several layers, from Greek to Latin and Arabic, and the developments continued after the high point of the 12th century (see Minnis *et al.,* 1988). Textual transmission took the form of systematic and often heavily glossed and commented versions of ancient knowledge. Commentaries reflected the logocentric mode of scholastic science, with a reliance on axioms, i.e., statements accepted as being true, though not necessarily so. The source of knowledge was 'that someone said so,' i.e., the 'Quotative.' Reporting the opinions of various authorities was an evidential feature of scholastic texts. The layered nature of medical learning showed in the hierarchy of authorities referred to. Galen and Hippocrates were frequently mentioned in learned and specialised treatises; next in frequency came Arab authors, such as Avicenna, Rhases, Haly Abbas, and Averroes, and medieval Latin authors. General references to doctors, leeches, physicians, and masters prevailed in more popular layers of writing (Taavitsainen and Pahta, 1998: 169).

Compilationes reflect logocentric science as well. This genre was important for the dissemination of knowledge and gained wide use in its different forms in the vernacular. Compilations had a twofold didactic function. First, they provided easy access to authoritative passages and convenient ways of finding important opinions. Second, they made the authorities available to readers not able to work their way through the originals (Minnis, 1979: 402–403). The two top genres of scholasticism approached one another at the end of the medieval period, and it is often difficult to make a distinction and classify texts. Textual histories of several works, including the *Articella* components, are extremely complicated and may include several layers, with commentaries and compilations intertwined. This practice of building upon various discourse forms was probably widespread. Alongside authentic texts, pseudo-authorial texts were written by near-contemporary authors and transmitted alongside the authentic ones; in addition, to elaborate the medieval genre map further, any important text in the Middle Ages could be subject to commentary.

Encyclopedias

The techniques of compiling reached a high level of sophistication in medieval encyclopedic treatises. They had multiple uses and audiences. The *De proprietatibus rerum* of Bartholomaeus Anglicus was originally composed in Latin (c. 1245) for friars to illustrate their sermons (Seymour *et al*., 1975/1988: 11). In addition to religious matters, it included natural history and medical lore; some copies, owned by high aristocracy, had handsome illustrations of medical practice and of the universe. A large part of the work overlapped with medical literature and seems to have served as a model for vernacular writing in the following centuries. A medical encyclopedia, the *Breviarum bartolomei*, was produced toward the end of the 14th century by London priest John of Mirfield. It recorded all medical authorities of the day, plus charms and prayers, perhaps reflecting hospital use (Getz, 1998: 50).

Questions-and-Answers Literature

'Questions literature' had several layers and traits with chronological developments. Teaching methods of universities, with their oral practices, contributed to the development of learned written genres. Conventions of scientific argumentation took shape: the *lectio* influenced the commentary, and oral disputations affected the question-and-answer pattern in written discourse. Theoretical and practical experience could be combined, e.g., Taddeo Alderotti's commentary was the result of 10 years of teaching with a long professional practice (Crisciani, 2000: 79). Likewise, Guy de Chauliac combined a university career with a long experience in medical praxis. Public disputes were central in communicating knowledge orally. Their written counterpart originally derived from Aristotelian treatises on scientific problems and became conventionalized at universities

in the 13th and 14th centuries. The formula of oral disputes was very similar to that seen in the written genre, and the influences intertwined, so that the medieval commentary also contributed to the development of the questions genre (Siraisi, 2001: 144–148). The pattern was elaborate: the question was posed, considered with pros and cons, given an affirmative or a negative answer, then expanded by descriptions, definitions, and explanations as well as a review of authorities. At the end, the main argument was raised again and the problem was answered. This pattern developed a standard stock of questions and remained valid for centuries (Cadden, 1993: 114; see also Minnis *et al.*, 1988: 212). Salernitan questions were in wide circulation and found in both verse and prose collections in Latin. The sources are complicated; some can be traced to Salerno, some to Montpellier and Paris, showing Arabic and Salernitan influences, and many seem to stem from classical collections of Greek problemata (Lawn, 1979: xiv–xxiii).

Pedagogical Dialogues

'Pedagogical dialogues' also derived from classical models but had different underpinnings. They were found in Greek literature, from Socrates through Plato and Aristotle, and continued throughout history, with Boethius's *De consolatione philosophiae* as the most influential medieval text of this genre. This "schoolroom colloquy between a master and a student" (Lerer, 1985: 19) set the model for the stereotypical roles in pedagogical dialogues for centuries to come and was translated several times into vernaculars (e.g., into English in the Old, Middle, and Early Modern English periods).

Case Studies, *Consilia*, and *Practica*

In the medieval period and for centuries afterward, the core of medical instruction was based on typical cases of disease. The genres connected with case reports were *consilia* and *practica*. The genre of consilia was modeled on legal documents and originated in the 13th century. A *consilium* was a piece of medical advice on a particular case. It offered a diagnosis and suggested a therapy (French, 2003: 121). *Practica* dealt with particulars of a disease and treatment and became a university genre with growing intellectual attention; the plague literature, for example, is connected with this genre. Surgical case histories were probably influenced by Arabic models and were not used in institutional teaching.

Vernacularization of Medical Writing

The complex motivations for vernacularization have received attention recently (see Wogan-Brown *et al.*, 1999). On the one hand, the processes seem to be connected with the rise of nationalistic feelings and the desire to enhance the status of the languages (e.g., Trevisa); on the other hand, it was a commonplace to apologize for the use of the vernacular for learned purposes in prefaces of early printed books. Latin scientific and medical texts provided the model for vernacular versions. Translations covered all levels, from academic texts to miscellaneous collections of useful materials such as recipes, rules of health, and applications of astrological doctrines, and some new texts were composed as well. Because vernacular languages were not used at the highest institutional level, the practical side became enhanced in them. In general, the transmission of surgical texts in the vernacular obeys laws which were different from those applying to Latin (Jones, 1989: 88). To date, this area has not been studied in great detail.

Learned Genres in the Vernacular

The learned genres of commentaries, compilations, and questions-and-answers were institutional. In the vernacular, these genres lost their original functions, and they may have gained new applications; such new uses and functions were central for dissemination of knowledge to the wider public.

Commentaries and Compilations

There are severe problems with identification of genres in vernacular languages. A recent discovery (Tavormina, forthcoming) revealed that even classical Greek authors' texts were translated into English in the late medieval period. The vernacular texts showed characteristics of the commentary genre but did not indicate their affiliation. The contrary seems to be even more common; some texts were explicitly called 'commentaries,' or the word 'comment' occurred in the title, but in contrast to genre expectations, the text contained explications of key terms and concepts so that the discourse features of the ensuing text were not in accordance with Latin genre features of the title. A survey of manuscripts indicated as commentaries in Voigts and Kurtz (1998) revealed that translations focused on the more utilitarian kind of academic texts, such as urinoscopies. Rather than quoting authorities and reconciling their views, these texts strived at making the contents easily accessible. The role of the translator varied; some seemed to have distanced the text (Benvenutus Grassus), and some acted as editors by selecting and excerpting materials, as in the case of John Arderne's surgical texts. There was no stability, and it seems that the genre was not conventionalized in the vernacular. It is evident that the conventions of taking responsibility for

one's opinions, drawing conclusions, and conciliating conflicting views, did not hold in vernacular texts, and many of them simply listed opinions of various authorities on a topic. Chauliac's top-level academic surgical treatises and the academic encyclopedia *Of the properties of things* represented the learned end of medical writing in the vernacular, and chronological developments can be detected in their transmission. Trevisa's translation (1398–1399) represented the early phase of vernacularization, whereas Wynkyn de Worde's edition was printed around 1495 and belonged to a different phase, when vernacular writing was already established. Adaptations were made for a broader audience; for example, pictures were added to act as visual texts, and the use of Latin in the rubrics was maintained as part of the scheme (Holbrook, 1998). The scope of encyclopedic treatises was wide in the vernacular. The focus of the more popular kind was on astrological medicine and its applications. Differences are obvious: learned *compilationes* assembled *loci communes* into coherent wholes, otherwise the technique merged with normal book-making practices. It was customary to gather useful texts, which also circulated independently, into the same manuscripts in so-called 'commonplace books.' The distinguishing feature of a commonplace book was its purpose: miscellaneous items were copied for the compiler's own personal use, interest, and amusement. The best example of this genre in medicine is the commonplace book of Thomas Fayreford (see Jones, 1998), but other commonplace books also included medical materials.

Questions-and-Answers and Pedagogical Dialogues

The elaborate patterns of Latin writing were not found in the vernacular, but because questions and answers were particularly suitable for instruction, the genre was adapted to vernacular teaching. The pattern was sporadically found in medical prose of the 15th century, but more consistently only in the 16th century. In these texts, the questions were straightforward, sometimes even blunt, and the answers came from some monological treatises, e.g., from Chauliac's surgical treatises in *Guido's questions* (1579). Questions and answers were found earlier in verse than in prose. Verse provided a more elementary mode of expression in Middle English, and prose was associated with philosophy and higher learning. An interesting work combining various literary and nonliterary genres is *Sidrak and Bokkus*, which circulated widely in several vernaculars in the 14th and 15th centuries. This treatise was an encyclopedic compilation with questions and answers, a philosophical dialogue with the roles of a teacher and a learner, and a saint's legend. It was written in rhyming couplets with common stock rhyme words and thus easy to memorize. Unlike learned encyclopedias, *Sidrak and Bokkus* was not coherent, but the 362 scientific and medical questions were dispersed in the text. Its dialogue has been characterized as a "cathecism" without conflict (Burton, 1998: 1:xxvii): the pupil accepts the teacher's answers without argument or further queries. Topics of Salernitan questions were frequently dealt with in vernacular writing as well, but they survive mainly in references to the school of Salerne in late medieval English-language medical literature.

Case Reports

Narratives of the course of illness are commonly found embedded in academic and surgical treatises, e.g., Benvenutus Grassus' learned opthalmology and John Arderne's texts. Recipes in remedy books may contain occasional case reports to prove the efficacy of the cure.

Remedy Book Material: Recipes, Charms, and Prognostication

Recipes were a well-defined procedural genre, but even their transmission was extremely complicated. Recipes were found on their own and embedded within a wide range of texts. Recipes in different traditions of medical writing in Middle English show different degrees of textual standardization: in remedy books, recipes followed a standardized format, but in academic and surgical texts they were more varied. The difference can be explained by the different functions of recipes in these traditions. In learned treatises they provided illustrations of healing practices, whereas remedy books served as handbooks for quick reference. The standardized format, with explicit titles and regular structure, served practical purposes and made consultation easier (Taavitsainen, 2001).

Conclusions

Vernacularization processes are complicated and need further study. The converging development of commentaries and compilations, for example, is likely to have taken place in Latin writing as the traditions of commentary and compilation approached one another. Medieval commentators were influenced by the practice of compilations; attitudes changed as works of revered authors were noticed to include compilations as well, and compilations acquired sophistication and refinement especially in the 13th and 14th centuries (Minnis, 1979: 386–387, 413). It is no surprise that commentaries and compilations

overlap and merge in vernacular texts and that it is difficult, sometimes impossible, to distinguish between the genres. Perhaps it is not even necessary to do so.

Compilations form a broad category in the vernacular. Some thematic compilations became fused with commentaries, and at the other end the process overlapped with the type of activity found in commonplace books. In general, vernacular medical texts had a bias to instruction and practical knowledge. There was a great deal of variation between individual texts. More theoretical treatises were also found, but there were difficulties in making vernacular languages function in the new prestige register. The late medieval period was important in establishing genre conventions in vernacular writing. In the 15th century the scale of medical writing was wide: there were texts with theoretical considerations transferred from the Latin exemplars, but there were reduced adaptations and applications as well. The difference between learned and popular layers of writing was reflected in some pertinent features of scholasticism, for example, the scale of authorities quoted and the degree of specificity. It seems possible to trace the transmission of scientific ideas to various audiences with a detailed comparison of the contents and styles of writing. More definitive conclusions need more studies on the Latin background and on features of vernacular writing.

Although Latin genres of writing have not been studied in detail, the situation is improving. A major research project of revising the Thorndike and Kibre Catalogue into electronic form is forthcoming (Voigts), and recent editions of Latin medical texts provide excellent material for more detailed studies. The scope of vernacularization in different European languages is not fully known yet and new discoveries are possible. New research tools have made the task easier and new projects have been launched. The database *Scientific and medical writings in Old and Middle English: An electronic reference* (Voigts and Kurtz, 1998) and George Keiser's volume *A manual of the writings in Middle English 1050–1500: Works of science and information* (1998) are invaluable in charting the extent of English medical writing and provide a good overview of the situation around 1500 A.D. An electronic corpus Middle English Medical Texts (Taavitsainen, Pahta and Mäkinen, 2005) makes a wealth of vernacular medical texts of the period available to scholars.

Medical Discourse: Hedges

K Hyland, University of London Institute of Education, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Hedging is the expression of tentativeness and possibility, and it is central to academic writing where statements are rarely made without subjective assessments of their reliability and the need to present unproven propositions with caution and precision. In medical writing, hedges play a critical role in gaining ratification for claims from a powerful peer group by allowing writers to present statements with appropriate accuracy, caution, and humility, expressing possibility rather than certainty and prudence rather than overconfidence. In a context where the accreditation of knowledge depends on the consensus of the research community and the need to evaluate evidence, to comment on its reliability, and to avoid potentially hostile responses, expressions such as *might, perhaps*, and *possible* can contribute to gaining the acceptance of research claims. Medical papers provide interesting and useful examples of the use of hedging in scientific discourse because they relate to matters impinging on significant issues of our lives.

In the past decade, a growing literature has demonstrated the clear pragmatic importance of hedging as a resource for expressing uncertainty, skepticism, and open-mindedness about one's propositions. Studies have revealed the significance of hedging in textbooks, scientific letters, science digests, and academic research papers (Hyland, 1998a, 1998b, 2000; Myers, 1989). Hedges have also been shown to play an major role in medical discourses by Salager-Meyer (1994), Skelton (1997), and Adams Smith (1984). These studies indicate how hedges represent a writer's *attitude* within a particular context and help negotiate the perspective from which research conclusions can be accepted. In this article, I will briefly discuss the importance and role of hedging in academic medical papers and sketch a framework for understanding the functions they perform for academic writers.

Medical Discourse: Hedges

K Hyland, University of London Institute of Education, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Hedging is the expression of tentativeness and possibility, and it is central to academic writing where statements are rarely made without subjective assessments of their reliability and the need to present unproven propositions with caution and precision. In medical writing, hedges play a critical role in gaining ratification for claims from a powerful peer group by allowing writers to present statements with appropriate accuracy, caution, and humility, expressing possibility rather than certainty and prudence rather than overconfidence. In a context where the accreditation of knowledge depends on the consensus of the research community and the need to evaluate evidence, to comment on its reliability, and to avoid potentially hostile responses, expressions such as *might, perhaps*, and *possible* can contribute to gaining the acceptance of research claims. Medical papers provide interesting and useful examples of the use of hedging in scientific discourse because they relate to matters impinging on significant issues of our lives.

In the past decade, a growing literature has demonstrated the clear pragmatic importance of hedging as a resource for expressing uncertainty, skepticism, and open-mindedness about one's propositions. Studies have revealed the significance of hedging in textbooks, scientific letters, science digests, and academic research papers (Hyland, 1998a, 1998b, 2000; Myers, 1989). Hedges have also been shown to play an major role in medical discourses by Salager-Meyer (1994), Skelton (1997), and Adams Smith (1984). These studies indicate how hedges represent a writer's *attitude* within a particular context and help negotiate the perspective from which research conclusions can be accepted. In this article, I will briefly discuss the importance and role of hedging in academic medical papers and sketch a framework for understanding the functions they perform for academic writers.

Hedging and the Construction of Knowledge

Hedging has been a subject of interest to linguists since Lakoff (1972) first used the term to describe 'words whose job it is to make things more or less fuzzy.' Essentially, it represents an absence of certainty and is used to describe 'any linguistic item or strategy employed to indicate either a) a lack of commitment to the truth value of an accompanying proposition or b) a desire not to express that commitment categorically' (Hyland, 1998a: 1).

The importance of hedging lies in the fact that transforming claims into accredited knowledge requires reader acceptance and therefore linguistic and rhetorical means of persuasion. Academic knowledge is now generally acknowledged to be a social accomplishment, the outcome of a cultural activity constituted by agreement between a writer and a potentially skeptical discourse community. As a result, the research paper is a rhetorically sophisticated artifact, carefully crafted to display a careful balance of factual information and social interaction, set out using community-recognized and -accepted argument forms. Academic writers need to make the results of their research not only public, but also persuasive, and this involves them carefully weighing claims for the significance and plausibility of their work against the convictions and expectations of their readers. Successful academic writing, in other words, involves authors evaluating their material and acknowledging alternative views because all statements require ratification. This, at least in part, depends on the appropriate use of various rhetorical and interactive features, of which hedges are among the most important.

These examples show how hedges can modify the factual status of a proposition to suggest that it is based on imperfect reckoning rather than certainty. provide an idea of how this is often achieved.

The hedges (italicized) indicate interpretations and allow writers to convey their attitude about the truth of the statements they accompany, thereby presenting unproven claims with prudence and softening categorical assertions. More than this, however, hedges open a discursive space in which readers are able to dispute the writer's arguments and interpretations, thereby enabling writers to take a position with respect to an audience as well as to facts.

The Functions of Hedging

Although medical research scientists gain and retain their academic credibility by securing readers' acceptance of the most significant claims that their findings will support, such strong claims are risky. Few assertions in the scientific world survive for long before being replaced by those with greater explanatory efficacy and there is always the possibility that claims will contradict or challenge the beliefs of one's peers. The fact that readers are able to reject claims means they have an active and constitutive role in how writers construct them, and it is the writer's anticipation of this potential opposition that makes hedging central to academic writing.

This opposition can be divided into two types and claims must address these to stand any chance of success. First, claims must correspond with what is believed to be true in the world. Hedges here are 'content-oriented' and concern the relationship between a proposition and a representation of reality. At a further level of delicacy, we can distinguish the obligation on writers to present their claims as accurately as possible and the equally pressing need to anticipate the dangers of overstatement. Second, a proposition that could be presented categorically from an objective perspective may be explicitly hedged because of reader considerations. Thus, 'reader-oriented hedges' incorporate an awareness of interpersonal factors. It is often difficult to pin down precisely what the writer intends, as indeterminacy is a widely recognized feature of modal semantics. However, although there is inevitably some overlap, it is useful to conceptually distinguish these three broad functions to understand the roles that hedges play in academic discourse and readers' motivations for employing them (Hyland, 1998a).

First, hedges allow writers to express propositions with greater precision in areas often characterized by rapid reinterpretation. Hedging here is an important means of attesting to the degree of precision or reliability of a claim and accurately stating uncertain statements with appropriate caution. In medicine, writing is necessarily a balance of fact and evaluation as the writer tries to present information as fully, accurately, and objectively as possible. Thus, writers often say '*X may cause Y*' rather than '*X causes Y*' to specify the actual state of knowledge on the subject. Hedges here distinguish the actual from the potential, or the known from the inferential, and imply that a proposition is based on the writer's plausible reasoning rather than certain knowledge. Readers are expected to understand that the proposition is true as far as can be determined.

The second reason for using hedges concerns the writer's desire to anticipate the possible negative consequences of being proved wrong and the eventual overthrow of a claim (Hyland, 1998a; Salager-Meyer, 1994). Academic reputations are built on making novel, interesting, and plausible contributions to

knowledge, which means stating the strongest claims possible for any particular evidence. However, writers also need to protect themselves against the hazardous consequences of overstatement. Hedges here help writers avoid personal responsibility for statements in order to protect their reputations and limit the damage that may result from categorical commitments. This usage follows Lakoff in associating hedges with 'fuzziness,' but I am using the term fuzziness here not to describe connections **between propositions**, but the ways that hedges can blur the relationship **between a writer and a proposition** when referring to speculative possibilities.

One way writers achieve this is to express claims using to employ evaluative *that* structures with modal devices and non-agentive subjects (Hyland and Tse, 2005). Most commonly, this involves the use of dummy *it* (see Example 7) or 'abstract rhetors,' which attribute judgments to inanimate sources (Example 8).

In the medical sciences, writers may hedge in this way because of preliminary results, small samples, doubtful evidence, uncertain predictions, imperfect measuring techniques, and other uncertainties in the experimental process or case histories.

Finally, hedges can be 'reader-oriented' in that they contribute to the development of a writer–reader relationship, addressing the need for respect and cooperation in gaining readers' ratification of claims. Research writers must always consider both the reader's role in accrediting knowledge and the need to conform to the expectations of the medical research community concerning limits of self-assurance. Most importantly, categorical assertions leave no room for dialogue and are inherently face-threatening as they suggest that the arguments need no feedback, thus relegating the reader to a passive role. By explicitly referring to themselves as the source of the claim, often with a cognitive or discourse verb, writers are able to mark the statement as one possible position, an alternative view rather than a definitive statement of truth, and thereby indicate a personal opinion awaiting verification. Examples 10 and 11 in provide illustrations. Here, hedges appeal to readers as intelligent colleagues, capable of deciding about the issues, and indicate that statements are provisional, pending acceptance by one's peers.

Thus, we can see that hedges help protect the writer against possible wrong interpretations or faulty results, but they also allow them to demonstrate an awareness of the reader's possible alternative viewpoint, displaying the conditional nature of statements out of strategic respect for them and indicating the degree of confidence that the writer judges it prudent to attribute to statements. In sum, though there is considerable overlap in these functions, hedging looks three ways: toward the proposition, toward the writer, and toward the reader.

Extent and Distribution of Hedging

This multifunctional importance means that academic medical writing is extensively hedged. The essentially rhetorical nature of these functions, however, means that there are considerable variations in the distribution of hedges across different genres, with greater concentrations in more argumentative and persuasive types of texts. In a study of different papers in the *British Medical Journal*, for instance, Adams Smith (1984) found that editorials and review articles are more heavily hedged than research papers and medical case reports. When qualifications are omitted, the result is both greater certainty and less professional deference, reflecting a different attitude to information and readers. Thus, genres that present information as accredited knowledge, such as undergraduate textbooks (Hyland, 2000) and popular science articles (Fahnestock, 1986), contain far fewer hedged propositions. The authors of such genres do not have to persuade an expert audience of a new interpretation or anticipate the consequences of being proved wrong because most claims already have factual status.

Similarly, hedges are differently distributed across different parts of each genre, with their use especially marked in the more discursive sections. They are particularly prevalent in the introduction and discussion sections of research articles and the comment section of clinical case notes, for example (Adams Smith, 1984; Salager-Meyer, 1994). It is here that writers are seeking to establish the relevance and significance of their research and the plausibility of their interpretations and is therefore where they need to be more tentative and circumspect in their assertions. There is also evidence that the type of hedges employed differ as well, with content-oriented hedges dominating the methods and results sections and more reader-oriented forms being found in introductions and discussions (Hyland, 1998a; Salager-Mayer, 1994). These patterns allow writers to convey approximations when discussing symptoms and methods and to evaluate, interpret, and comment on the evidential status of their information in the discursive sections.

Conclusion

In this article, I have discussed some of the contextual factors that shape the ways writers say what they believe and want others to accept. I have tried to

show that the expression of doubt and possibility is central to the negotiation of claims and that what counts as effective persuasion is influenced by the fact that evidence, observations, data, and flashes of insight must be shaped with due regard for the nature of reality and their acceptability to an audience.

Medical Discourse, Illness Narratives

L-C Hydén and P H Bülow, Linköping University, Linköping, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Introduction

During the past decades, the health field has become a battlefield where alternative concepts of illness, health, and treatment compete with the dominant traditions of Western scientific medicine. New health care practices such as complementary and alternative medicine have gained status. Etiological factors have come to include 'lifestyle' factors, as in the relationship between smoking and lung cancer or the relationship between stress and certain coronary diseases. Patients have access today via the Internet to sources of information that were previously unavailable to them and can approach their physicians with more knowledge and new demands.

As part of these changes, researchers have become interested in questions having to do with the relationship between, on the one hand, the patient and his or her illness and, on the other hand, traditional scientific medicine and its concept of diseases. In this context, the study of illness narratives has gained prominent status.

Research on the forms and functions of illness narratives has expanded rapidly since the early 1980s. Its development is marked by diversity in the theoretical perspectives and methods that are brought to bear on a variety of problems.

Illness narratives is a wide field encompassing interview studies of patients' narratives of illnesses, studies of the way that narratives are used in the interaction between medical staff and patients, and clinical studies of how narratives could be used by medical professionals in encounters with patients. Another field of study that has emerged is the study of written and published illness narratives; Hawkins (1993) called these pathographies.

Theoretically, researchers have been interested in the narrative as an opportunity to study the subjective experience of illness, the way in which identity is reconstructed narratively in the face of illness, and how the institutional context affects the relationship between medical professionals and patients. This is especially interesting in terms of power and the patient's ability to make his or her voice heard in the medical encounter. Thus, researchers focus on narrative structure and coherence, as well as on the functions of narratives in various social contexts.

Two Voices

A central problem area for many studies of medicine and illness narratives is the relationship between what is called the voice of the lifeworld and the voice of medicine. These concepts were introduced by Elliot Mishler in his book *Discourse of medicine* (1984). Mishler pointed out that in the discourse of ordinary medical interviews it was possible to discern two

Medical Discourse: Non-Western Cultures

J Clarac de Briceño, University of the Andes, Mérida, Venezuela

© 2006 Elsevier Ltd. All rights reserved.

The term 'shaman' has its etymological root in the word 'saman' from a Manchurian language, meaning 'one who knows.' Originally the term was used in various areas of northern Asia and was later brought to the Americas, to the southeastern part of India, and to Australia and Africa. According to Mircea Eliade, shamanism or the socially specific role of the shaman was brought to the Americas by the first eastward waves of immigration from Asia. The origin of the shaman in America (the continent in which the role has been most studied) is well documented (see Eliade, 1974: 266; Lowie, 1934: 183–188).

The role of the shaman is not limited to individual practice. It is currently portrayed in the literature as a category of social activity with a legitimate function as a health care phenomenon. Classifications include legal aspects, health program functions, adaptation in the migration of ethnic groups, and shamanic practice in the integration of tribal peoples and their customs into the social mainstream. As such the role of the shaman has become an interdisciplinary study.

Elaborations in the area of anthropology and ethnopsychiatry have focused on therapeutic aspects and role models which include the magical or nonlocal physical aspects of shamanic activity. These include Geza Roheim (1950), Mircea Eliade (1951), Claude Lévi-Strauss (1958), Alfred Métraux (1967), George Devereux (1970), and others who treat aspects of hypnotic suggestion or trance as therapy.

Mircea Eliade: Ancient Techniques for Producing Ecstatic States

Eliade is the great classic authority on shamanism, and is recognized as such by those who wrote after him. His *magnum opus* (*Shamanism and the ancient techniques of extasis*, 1951) is the first attempt to comprehensively approach the subject from the point of view of a religious historian. His sources include works on what is described as classical shamanism in Siberia, the Americas, Indonesia, and Oceania.

Mystical experience is central to his theme, in which he emphatically rejects the proposition of

such experience as neurotic, as has been held by some psychiatrists and ethnopsychiatrists. His concept of techniques for producing ecstasy is presented as being in the ancient magical tradition of the fire element and the symbol of the veil. He treats initiation into the mysteries in its various forms as well as the so-called secret societies which are concerned with such rites. The token death and resurrection of the candidate, including seclusion, the use of the funeral mask to indicate the passage of the shaman into the realms of the dead, token burial, and the descent into the nether regions called hells are also discussed. The hypnotic dream or trance and the obstacles which must be overcome to reach this state, such as the abandonment of previous lifestyles so that curative powers can be achieved, and the intonation of songs which tell of the adventures of the way into the spirit world and the spheres of the gods, are elaborated as part of shamanic experience everywhere.

Shamanic Trance

Induced suggestive states are widely employed for both lay and religious purposes in all cultures, particularly in the Native American and mestizo Latin American. The ancient Greek Dionysian mysteries and the European transition into Christianity used trance and mesmeric techniques which are still in wide use. The so called 'epidemics of possession,' such as outbreaks of demonic possession and the witch-hunts of the Middle Ages and Renaissance, are later developments.

Judeo-Christianity has a tendency to reject religious trance as pythonic and for this reason all devotees of the current autochthonous religions are condemned as superstitious in the Celto-Germanic persuasions. This condemnation extends to members of the Catholic priesthood who have shown a tendency to stray toward induced states, although some religious practitioners have been given lay recognition and are treated as sainted by various cults.

Trance is variously delineated in European languages as possession, hysteria, dissociation, altered consciousness, or elevated states, all of which may be researched as multidisciplinary anthropology.

The Deployment of Symbol in Shamanic Healing

Lévi-Strauss (1961) uses the term 'symbolic efficiency' for effects produced by shamanic therapy, such terminology being opposed by Jean Chiappino, who claims that the significance of actual physical treatment is underplayed. (Chiappino, 2003: 39). Symbolic efficiency concerns psychological effects produced at the symbolic level as an isolated holon. Trance and the shamanic song are outstanding in psychological cure and include group participation.

Contemporary anthropologists point out that there are mystical and mythical aspects in all therapeutic cure including the most scientific, and that both mysticism and the archetypal roots of myth constitute the paradigm and provide the dynamics required for all healing.

Shamanism and Neurophysiology

Insofar as objective efficiency and scientific proof are concerned, since 1975 neurophysiology has demonstrated the existence of endogenous processes that inhibit nociceptive sensitivity and produce opiate substances that inhibit pain. Endorphins secreted by the pituitary gland and by cells in the brain act on pain receptors in the entire central nervous system so that pain is reduced. The endogenous interaction between receptors is accomplished by peptones called encephalins, such as endorphin and dimorphine. Researchers conclude that there are processes that trigger receptors at a substrate level which also contribute toward inhibiting the transmission of pain information throughout the central nervous system. The human body is thus seen to be naturally equipped to reduce pain sensation.

The neurophysiologist James L. Henry of the Department of Physiology and Psychiatry at McGill University has remarked that symptoms commonly associated with such states may include the activation of endorphins, and that it seems reasonable to suppose that this interaction involves a particular mechanism with an extension or global effect within the brain. Two shamanic symptoms appear outstanding to Henry: (a) detachment or separation from the physical world, that is to say dissociation which results in euphoria or ecstasy, and (b) immunity to physical pain, even the most severe. He has found that in states of altered consciousness endorphins excreted from the pituitary gland are present in the blood. This research opens the way to a multidisciplinary approach for anthropologists, neurophysiologists, and psychiatrists.

Shamanism and Ethnopsychiatry

Geza Roheim, an outstanding ethnopsychiatrist, has concerned himself with an ontogenic theory of culture. Largely influenced by Sir James Frazer (*The Golden Bough*, 1890) and his unilineal evolutionary concepts, Roheim considers the shaman as a psychiatric pioneer: "the scientific precursors who held that the human being was capable of matching his

strength against the world" (Roheim, 1982: 80–81). He categorizes the shaman as a schizophrenic. After reviewing the case of a schizophrenic patient at Worcester State Hospital, Worcester, Massachusetts (1938–1939), he drew parallels between shamanic fantasies and hallucinations observed in Oceania and in the Yumas of California, as well as those of the Australian aborigines. He has said that the attitudes and behaviors of those concerned with magical practices are related to symptoms observed in states of neurosis. His theories of ontogenic culture are based on the effects of prolonged infancy in the human being and the trauma produced by the exaggerated dependence which is generated upon the relationship with the mother, making it impossible for the child to experience pleasure in sexual interaction. Culture then becomes a permanent search for a mother substitute because the mother archetype has not been individuated. Magical fantasy and schizophrenia are related although the former deals with an empirical world while schizophrenia deals only with substitutes.

Special emphasis is placed on oral magic, which is defined as healing through suction, and this is particularly applicable to the therapeutic work of the shaman, whom Roheim describes as one who assaults the mother's breast, the patient in this analogy being the mother, or the person who has never individuated the mother in the psyche, and the shaman being the suckling child who is the healer.

George Devereux: 'Sacred Disorder'

Devereux proposes a concentrated psychotherapy which will result in a cure rather than in mere accommodation, which is according to him the usual outcome. As an ethnologist he insists that any given culture should not accept as normal a situation which is virulently pathological. At the same time, he suggests that the Western psychiatrist should not impose his views on cultures which are not Western. Devereux is somewhat contradictory since he recommends culture-specific values while treating the shaman as a universal archetype.

'Sacred disorder' is classified as neurosis or shamanic disorder and this is likened to schizophrenia. He affirms that it is diagnostic error to classify individuals as neurotic or psychotic who because of their ethnic conditioning behave in a manner that is considered pathogenic in Western psychology. At the same time, he discusses shamanism in terms of psychopathological disorder, claiming that the shaman is severely neurotic bordering on psychotic in temporary remission, and one who is often in conflict with his own culture. He goes on to say that the shaman must himself be cured because uncured he is a social nuisance and that the only difference between a shaman and a psychotic is that the shaman's conflicts are expressed at the level of a cultural model rather than at the level of unconscious idiosyncrasy.

The curing of one shaman by another cannot be considered actual but is rather a restructuring of conflicts and symptoms according to their own convention without a conscious understanding of the nature of these conflicts and also without achieving any sort of true sublimation.

Anthropologists claim that Devereux takes an ethnocentric position because he believes that the shaman must sublimate in order to be cured (as Freud points out). The question remains as to why this Western value should be applied in a non-Western community which sustains a belief in a shaman who has been cured or indoctrinated into Western processes. Ethnological aspects in a situation where there is crosscultural exchange cease to be meaningful. Furthermore, Devereux fails to recognize the importance of the consensus of the cultural group, which has always been an anthropological consideration. The shaman cannot be limited to the mores and values of a marginal group in any given society or culture since adaptions have been made for reasons of efficiency in the protection of his own people against the constant inroads of Western value systems. Very often the non-Western group finds itself surrounded by political and economic forces which have invaded the community without its consent. This was often the case in the latter part of the 20th century in Latin American countries, where there are large unassimilated indigenous populations.

Devereux's concept of structuring mental disorder in accord with universal cultural mores is not practical since under actual conditions any cognitive apparatus employed must cover each particular ethnic difficulty. This cannot be done by resorting to the mores of an assumed metaculture. Such an *a priori* model may well bear an inadequate correlation to the actual state of knowledge with respect to human potential as it exists in the specific culture and will be biased toward a Western viewpoint. Eliade and others reject the concept that magical therapeutic events are pertinent to categories of mental disorder.

The New Shaman

It has been thought that shamanic lore is culturally specific and, since it is steeped in tradition, not affected by Western thought. This is not the case, since in the second half of the 20th century, communities which rely on the shaman had their geopolitical and cultural space invaded by large dominant cultures. Thus, in

order for the shamanic culture to prosper in the face of changes in political thought and modes of health care, the shaman has had to adopt methods of defense and to transform his role in order to harmonize with the cultural milieu propagated by the mass media.

The first transformation is in the community proper, which adopts new techniques that have been employed by other shamanic communities. The new shaman is fashion conscious and is aware of communities which speak various languages. In Venezuela, voodoo from the Afro-Caribbean and Brazil mingles with the rites employed by the priestesses of Maria Lionza. A spiritual brotherhood is inaugurated and is maintained by travel as well as through electronic media.

The shaman leaves his own community to impose his ideas and methods on other communities, including sections of the mainstream culture (which increasingly makes use of his knowledge). A feedback loop becomes established between cultures, particularly in Latin America. Thus a defense is established not only of shamanic lore but also of the traditions within the whole culture. The shaman can operate within the legal systems imposed upon medical services, which impose licensing and qualifications required for practice. In order to maintain social dignity within the body of a multiethnic and pluricultural society and to protect himself from aggression, the shaman has linked his role with organizations that support indigenous cultures at national and international levels. Such organizations acquire an ever-increasing amount of power and influence.

Cults of possession, such as that of Maria Lionza, which has been popular in Caracas since the 1970s, adopt shamanic techniques and the leaders often use the title of 'shaman.' These cults proliferate throughout Latin America and Africa, although these new aspects of shamanism have so far been studied only superficially.

The phenomenon which has come to be widely designated as possession uses trance-inducing techniques which stem from shamanic traditions. However, the various cults differ from the shamanic tradition, since the shaman uses the trance as a means of transcending himself so that he may enter the spirit world and become a medium for higher powers of inspiration. Inversely, cults of possession do not attempt to transcend but rather to bring the higher powers down or to invoke communication so that the spirit enters the body or inspires the mind of the shaman or medium.

Shamanism and the Cult of Possession

In the cult of possession, which is again a distinct form of shamanism, any manifestation of disorder is restructured so that communication is possible at a new level. Most psychiatrists consider any sort of possession to be psychopathological and related to hysteria. François Laplantine (1975: 23) defines possession as "psychosomatic conversion of an unconscious conflict into a symptom." He understands possession as a realization of a conversion which is not hysteria but its contrary: "it expels the symptom and fills the body of the entranced dancer with a social and cultural language." Because hysteria denotes a sort of suffering, he further denotes possession as "the fervent celebration of myth."

The ethnologist Louis Price-Mars considers possession to be a crisis which he terms 'teolepsia,' "a metamorphosis or normal psychological state which reproduces aspects and mannerisms of the gods within the context of a dramatic personification." Like Laplantine he insists on the distinction between religious possession as it is seen in Africa and the Americas, and possession as hysteria, which is clinical. Hysteria is a common disorder while possession implies religious rites of some sort. Possession can also be described as a semiotic sign with the signified being the spirit or the god which manifests in a ceremonial context with percussion instruments, dance, song, aromatics, tobacco smoke, candles, and other appurtenances of the sacred.

Roger Bastide: Adorcism and Exorcism, Shamanism A and Shamanism B

Bastide (1972: 72) makes the distinction between trances which occur through possession as adorcism, which is the imposition of a new soul or spirit into the person, and exorcism, which is the extraction of a spirit which is causing harm. Exorcism is a widely practiced shamanic technique (in some regions of the Americas called 'bad air exorcism') and consists of suction or a sucking action accompanied by the sounding of a sacred *maraca* or rattle made from a gourd filled with seeds or stones. Bastide describes shamanism A as adorcism, the possessive trance which transports the shaman to the spirit world to recover the soul of the patient which has been stolen by spirits. Exorcism is designated as shamanism B. The shaman (priest or medium) is capable of performing both A and B.

Bastide includes what he calls the 'savage trance' and also the 'baptized trance.' This is a distinction which reflects attitudes of the African slave when presented with shamanic practices, the traditional and the introduced. The traditional savage entered into an uncontrolled trance which was involuntary and without any kind of social projection; the baptized trance was the result of a long and arduous

training which capacitated the recipient or initiate to become socially useful in a new situation.

Classifications of the Trance

Trance can be classified either as disassociative, or as euphoric or theatrical. Disassociative trance is asocial in character and indicative of biological or cultural states which are pathological, or again may be the first indications of a tendency toward shamanic initiation.

The euphoric trance is achieved by the shaman after initiation, and permits a cultural channeling of the disassociative, enabling the practitioner to invoke the trance at will and give it a therapeutic character, which is expressed both biologically and psychologically in a socially therapeutic manner (biopsychosocial). The phenomenon is endogenous or introverted and is culturally accepted. It may be brought on with or without external stimuli such as hallucinogenic plants, tobacco rituals, incense, candles, flute music, the drum, the *maraca*, song, or prayer, and may include the employment of sacred objects such as cords, collars, crucifixes, sacred images, dolls, necklaces, capes, or gunpowder, and massage and hypnotic manipulations of various sorts. Euphoric trance is socially cultivated and is much venerated. Shamans who are in charge of these rites are highly respected and adulated with varying degrees of awe in respect of the sacred character of their office.

Nevertheless, the shaman, or *mojan* as he is called in Spanish, or the American *piache* or priestess does not always truly 'go under' or enter into the trance but, being familiar with each step of the process, is able to imitate the behavior as part of being a therapist without the patients or the faithful being aware of any guile. Such histrionics may well be classified as theatrical trances and often imitate the euphoric trance perfectly.

The transformations of the shaman are various, both in trance states and out of them, and these variations are often changed by apprentices, adepts, and priestesses, who are all aware of global changes, political and ethnic. Thus the student or the investigator should not attempt to categorize fixed shamanic practice, but rather observe the ever-changing scenario which is even now unfolding, and to note carefully one's own reactions to these new sociocultural conditions.

Western medicine, including biomedicine, has shown a tendency to deprecate traditional or natural medicine. The shaman and folk doctors are often ignored or considered as quacks who lack education and information. Some scholars, such as O. Carl Simonton, think, rather as does the neoshaman and the folk medicine practitioner, that the devotion to technology and the dogmatic principles of the medical profession have lost the sense of what it means to be human. Medical science and medical schools based upon mechanistic or material principles have become clinically impersonal, and ignore the cultivation of a *gestalt* approach. This is nothing new; Plato put it quite clearly: "So neither ought you attempt to cure the body without the soul, and this is the reason why the cure of many diseases is unknown to the physicians of Hellas, because they are ignorant of the whole, which ought to be studied also; for the part can never be well unless the whole is well" (Plato, *Charmides*, 156, 157.)

The Shaman, Myth, and the Cosmos

The shaman in all forms and manifestations is respected and highly esteemed in his own community and in other similar ones as well as in mainstream society. In some cultures the shaman is seen as the representative on earth of the Cosmic Creator and so plays the role set out in the sagas for the culture hero at the conception of the world. In trance he enacts the creation of human beings and the relations which they had with the spirit world at the beginning of time. Because the shaman has the ability to communicate with spirits or motivating forces he is able to perceive more clearly the pathogenic agents which debilitate his patients and is able to neutralize them. Patients or the faithful are led to confront the psychological dangers to which they are exposed during the sessions at which they are cured.

Shamanic societies interact through their myths with the whole region of cosmic space, where there are various heavens overarching various mountains and sacred lakes. In the Himalayas the gods of the people continue to dwell, as do the spirits they command and those of the dead. Places such as those known as the Houses of Thunder are domains in which the Sun and the Moon move in their roles as mythic heroes. In the Andes there is the home of the double rainbow, male and female, which is the symbol of the bridge across the chasms of the many cosmic spaces which yawn between the heavens and the Earth. These the shaman negotiates as he or she passes from one space to another or passes to the Houses of the Grandfathers to visit the Old People. There the first humans, who have continued to exist from the beginning of time, find their abode and thence upon occasion descend to dance with their offspring. There live their companions, the mythic animals and birds, the eagle, the anaconda, the rainbow serpent, the quetzal, and the bear.

This belief in the Old Ones is common throughout the Americas from south to north. Viewing this area

as a cosmic space, according to Eliade, fire has a primordial role, particularly in South America. However, earlier research has shown that in South America the elements of air and fire take a preponderant role in the cosmology and shamanic ritual. Fire is described as a glimmering, or as a beam or flame seen to exist within the air, the primordial element from which emerged the first gods who came to Earth. The primordial elements are of the same physical constitution as the gods, the spirits, and the enchanters with which the shaman works and whose language he has learned as part of his initiation. Through this knowledge the shaman brings rain, commands the thunder, and calms the storm. The shaman knows the sacred language because he or she has become familiar with the primordial sounds, those of nature which cannot tolerate the noises of human beings. It is for this reason that the shamans of the Andes recommend silence when walking in the highland meadows and beside the lakes.

The shamanic veil is also conceived as a cosmic element and has become the object of research, although not always mentioned as such. There is some discussion of spiritual helpers or allies with which the shamans work and which are often described as spirits of nature. The various airs, the spirits of the water, of the rivers, the spirits of the Sun and Moon and of the rainbow are all called upon. In the northern part of South America, in Colombia and Venezuela, metaphysical persons fly like eagles when they come from the realms of the spirits and like vultures when they fly from the lakes of the dead.

There is a well-defined relationship between the shaman and certain birds. In the Venezuelan Andes, this alliance this has been portrayed as a winged stone, usually of serpentine (hydrous magnesium silicate) although sometimes this symbol is worked in gold. The shaman hangs this symbol from the elbows or around the neck when dancing alone or with a group. Flight often has to do with the search for the soul of a patient, a soul that has been stolen by a spirit or by someone who has died. This search is sometimes performed as evocation, the shaman calling back the soul of the patient, which is less dangerous than the shamanic journey in its quest.

The process of drawing out or of suction, used traditionally to relieve illness in the body of the patient, and the object which is regurgitated as proof of the extraction vary in different geographical regions and from one shamanic society to another. In general these objects take the form of parasitical worms or tangles of blood-soaked hair, the object being spat into a bucket of water, since water, particularly in the Andes of Venezuela, is the principal ally of the South American shaman.

The shamanic methods for healing by means of the imagination may be summed up as trance, flight, song, imagery, hypnosis, meditation, dance, tobacco, regurgitation, and the use of hallucinogenic plants (peyote, the San Pedro cactus, ayahuasca, yopo, and fungi). The power of the symbols which are considered to be contained in these substances permits the *mojan* or shaman to intuitively hear messages from the combined body-mind-spirit, which has been disregarded by Western medicine. However, the scientific realm in the eyes of the common people has its own symbolic powers: the white lab coat and the stethoscope are seen by mediums in trance as apparatus borne by doctor spirits (particularly in the cult of Maria Lionza) which they use on their patients with cold-blooded aplomb.

Every shamanic culture maintains certain objects and rites as ideals which have the potential for conveying physical forces, and the various objects function in proportion to the amount of mental or spiritual energy invested in each symbol. In every society there is that which has potential curative power and that which does not.

In multiethnic societies such as those in Latin America, each group identifies with not just one complex of belief objects as having real authenticity, but the participation is with various beliefs and the paraphernalia pertinent to each one. There is no sense of logical or religious contradiction in respect to any participation. Seen thus, shamanism must be studied within the new sociocultural contexts to which it has had to adapt in order to survive.

Medical Discourse: Sociohistorical Construction

Introduction

Scientific language and discourse emerge in a cooperative and competitive struggle among scientists to create the knowledge base of their field, to establish themselves in relation to other scientists and to other professional groups, and to gain influence and control over political and socioeconomic means. In every strand of human communication, language and discourse play a role in the formation of a social and societal reality and identity. This is also true both of the formation of the different professional and vocational cultures within working and public life and of the formation of different academic cultures.

Historically, language has played a central role in the creation of different professions and academic disciplines, and it continues to play an important role in the development and maintenance of professional and institutional cultures and identities. Societal, social, and cognitive factors all make important contributions to the construction of professional cultures. Professionals try to create a space for their field within society. They try to establish themselves in contact and competition with others within their group as well as with other groups. Their knowledge base and its linguistic forms are created in a societal and social framework.

Diachronic Studies on the Development of Scientific Genres

A constructionist perspective on the emergence of scientific discourse and text genres is found in various traditions. Within the tradition of sociology of science, several studies have been devoted to analyzing the role of texts in the establishing of scientific fact. The scientific field is seen as a workplace, a laboratory, where social rules determine the establishing of facts and the rank order of the scientists. Knorr-Cetina (1981) was one of the first to describe the writing up of results as a process of tinkering with facts rather than a knowledge-guided search. Latour

Medical Discourse: Psychiatric Interviews

B T Ribeiro, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil and Lesley University, Arlington, MA, USA
D de Souza Pinto, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Psychiatry, defined as "the branch of medicine that focuses on the diagnosis and treatment of mental illness" (Andreasen and Black, 1995: xi), examines mental disturbances that afflict the patient/client in his or her relationship with himself or herself, family and friends, and society at large. It relies on the psychiatric interview as its key diagnostic instrument given that laboratory exams do not provide evidence for psychopathologic processes. The anamnesis – a procedure through which the doctor assesses and evaluates the patient's situation – structures the psychiatric interview and its clinical interpretations (Sullivan, 1970; Shea, 1998). The purpose of the interview is to detect patterns of affect relations that may trouble the patient, to make a diagnosis, and to prescribe a treatment. The doctor has an active question-asking role: he or she follows a series of pre-established steps that make up the diagnostic exam. Such steps follow specific topics (eating habits, sleep and sleep functions, parenthood, and vocational history, among others). However, it is the quality (rather than the quantity) of the doctor's questions that qualify him or her as an expert in the patient's perspective (Shea, 1998: 35). For the patient, certain questions or issues are of great importance. Some can be captured as requests for help and attention with an implicit message 'Can this person help me? Will she listen to me?' It is not surprising, therefore, that successful interviews may often close with an acknowledgment by the patient of 'having been listened to.'

Compared with medicine in general, psychiatry derives its practice from clinical observations of patients' behavior that take place in face-to-face encounters between patient/client and therapist/doctor (Shea, 1998) where language and communication disorders are closely investigated (Andreasen, 1979). It is also based on interviews with patients' partners, relatives, and/or friends. As key components of the mental status examination, language and cognitive behaviors are routinely assessed in the interview (Andreasen and Black, 1995: 49). Thus, psychiatric definitions related to thought, language, and communicative disorders (i.e., poverty of speech, pressure of speech, distractible speech, tangentiality, incoherence) derive from the clinician's observation and experience. Also, the doctor infers the patient's thought disorders from the patient's speech as thinking cannot be observed directly (1995: 68). Such understanding assigns a prominent role to language studies in psychiatry, where researchers in linguistics can contribute to more accurate and adequate descriptions for language and cognitive disorders.

Given the absence of specific diagnostic laboratory exams (common in other medical specialties, such as oncology, heart disease, and diabetes), this field of medicine relies on the expert's interpretive practices of the patient/client's symptoms (Sullivan, 1970). As Kleinman (1988: 7) states, "a psychiatric diagnosis is an interpretation of a person's experience ... whose roots are deeply personal and physiological." Thus, interpretation may differ for professionals with different orientations (for example, a psychiatric interview performed by a neuropsychiatrist contrasts with an interview conducted by a psychoanalyst). Such differences attest to the experience of illness as a culturally shaped phenomenon mediated by language. Discourse analysis of psychiatric interviews (Ribeiro, 1994; Pinto, 2000) provides relevant information on the use of language, communication disorders, and interpretive practices.

The Psychiatric Interview as a Speech Event

A psychiatric interview is a complex institutional encounter (Sullivan, 1970; Shea, 1998). For the psychiatrist, the interview aims at gathering the patient's information to reach a diagnosis and establish a course of action for proper treatment. An agenda should be followed to address and assess topics related to why the patient has been hospitalized, the history of the illness, and its previous episodes, among other clinical concerns. It is framed as an inquiry and not as a conversation. For the patient, however, this social encounter is seen as an optimal moment to introduce topics on health and illness, where personal stories emerge, and the doctor is framed as a potential listener (Ribeiro, 2002). These differences in expectations are usually not resolved. Most often than not, the institutional discourse prevails, with its key communicative goals: to diagnose and prescribe.

Research on the clinical interview has developed mostly from anthropology, sociology, and sociolinguistics, related to concerns on communicative practices that constitute human social life. To understand the social construction of the interview, the

concepts of speech event (Hymes, 1967) and speech activity (Gumperz, 1982) seem particularly interesting: "activities, or aspect of activities, that are directly governed by rules for the use of speech" (Hymes, 1967: 19). Research in these fields has shown that participants' roles, their rights and responsibilities in the course of the interaction, expectations about ways of introducing information, and constraints on content are all based on culture-specific norms. Thus, a well-established set of cultural conventions governs this social encounter and allows both the doctor and the patient to face the interview as an acknowledged clinical practice. The sociolinguistic analysis of clinical discourse also resonates with Sullivan's (1970: ix) definition of psychiatry as "the field of the study of interpersonal relations, emphasis placed on the interaction of the participants in a social situation." He added that "the psychiatric interview is a special instance of interpersonal relations" (1970: ix). The purpose of the interview is to find out who the patient is by reviewing the course of events that he or she has gone through in order to be who he or she is.

The DSM – A Unidirectional Model for Communicative and Speech Disorders

The *diagnostic and statistical manual of mental disorders* (DSM; American Psychiatric Association, 1994), a standard classification for mental health problems, provides a widely recognized reference for the psychiatric interview. It is based on the belief that mental disorders are universal and that they have a clear course of predictable symptoms. Additionally, its definitions focus solely on the patient, seldom taking the doctor–patient interaction and relationship into consideration. For example, a definition of a disorder known as flight of ideas, "instances of behavior where the patient may shift idiosyncratically from one topic to another and where things may be said in juxtaposition that lack a meaningful relationship" (Andreasen, 1979), does not take into account complex topic negotiation processes between the two participants; it focuses rather on the immediate prior context (i.e., a sequential response to a question).

Social and clinical researchers have questioned the DSM framework. Based on crosscultural studies of mental disorders, anthropologists and psychiatrists (Kleinman, 1988; Good, 1994) claim that there are cultural variants in the expression, course, and outcome of mental disorders. Social responses to the illnesses reveal cultural differences in the way a disorder is interpreted and handled. According to this approach, "abnormality and pathology are inseparable from cultural interpretation" (Good, 1994: 35) and the standard notion of normality must be assessed within a cultural context. Language is then conceived as a fundamental tool for understanding how human beings experience mental disorders.

The Interactional Model for Communicative Studies: Implications for Psychiatry

The interactional model for communication studies (Schiffrin, 1994) brought to light aspects of communication that have implications for psychiatry. It states that both speaker and hearer play active roles in everyday face-to-face interactions, as they jointly produce meaning and discourse. The situated nature of communicative behavior (verbal, nonverbal, and paralinguistic) is also foregrounded. Everything that happens in an interactive situation displays information, regardless of the speaker's intentions, and might be interpreted accordingly. The hearer then assigns meaning based on multileveled interpretations (semantic, pragmatic, conversational) to "whatever information becomes available" (1994: 401). The goal of an interactive situation then shifts from **the** interpretation of linguistic information encoded by the speaker to **an** interpretation of situated behavior. For psychiatry, this alternative model of communication has relevant contributions. It underscores that human communication relies on both the message – what is said – and how it is encoded. Pause, hesitation, gaze, and intonation are some of the cues the psychiatrist needs to attend to in order to assign interpretations to the patient's behavior. Also, interpretations are negotiated, repaired, and changed through interaction rather than unilaterally conveyed. Coherence thus might be assessed based on the different levels of communication: semantic (attending to the message, to what is being said); conversational (focusing on the sequence of conversational moves, i.e., question/answer); pragmatic (whether certain utterances are appropriate and relevant at a certain point of the interview); and interactional (the discursive strategies used by participants in the joint construction of talk).

The interactional model of communication also calls for a balance between the institutional agenda introduced and maintained by the doctor, on the one hand, and the personal topics brought up by the patient, on the other, allowing for a more conversational encounter, where the patient can introduce narratives and the doctor can align himself or herself as a listener of stories.

Based on transcripts of audio and videotaped psychiatric interviews, Ribeiro (1994, 2002) and Pinto (2000) have systematically analyzed the discourse of doctors and patients by using both topic analysis and narrative analysis. The former has pointed to different types of topic discontinuity, which reveal psychopathological problems regarding thought

disorders (such as tangentiality); the latter discusses common phenomena in everyday conversations such as digressions, often evaluated by clinicians as a progressive deviation from the topic in relation to the information flow of an assessment interview. Ribeiro (2002) suggested that a narrative might accomplish textual and conversational coherence, when the doctor aligns himself as both a conversationalist and an inquirer, attending both to his clinical agenda and to the patient's story.

Language, Thought, and Communication Disorders

Psychiatry is driven by diagnostic procedures. The doctor must investigate each one of the patient's symptoms and search for a standard definition. Part of this work is performing an assessment of thought, language, and communication disorders, as disturbances in the use of language are displayed in several psychiatric conditions, such as mania, severe depression, organic disorders, and schizophrenia (Andreasen, 1979; Shea, 1998).

The psychiatric diagnosis investigates pathological processes that underlie the patients' mental and psychological states. It is based on phenomenology, "the empathic method for eliciting symptoms" (Sims, 1995: 5). According to Jaspers (1963), we have only indirect access – the patient's own descriptions – to what happens to a patient; these descriptions are then compared and interpreted according to our own experiences. The patient's words (conveyed through statements, queries, complaints, etc.) are, therefore, reinterpreted in light of our own understandings. Hence, the task of providing a psychiatric diagnosis is an extremely complex activity. It involves mainly the doctor's ability to unravel and understand the nature of the sufferer's experience, given the absence of laboratory exams to sustain the diagnostic hypothesis. The psychiatric diagnosis is the key reference point for understanding the patients' condition and related therapeutic procedures.

The psychopathological examination – which unfolds in the psychiatric interview – plays a key role in the psychiatric diagnosis. It assesses the patient's attitude toward the interview, that is, whether he or she is being cooperative. It investigates memory, consciousness, attention, orientation, and language and thought processes, etc. Aspects related to pressure of patient's speech, rhythm, and the use of very long pauses are classified as speech disorders. Another range of disturbances – thought disorders – relate to how thoughts are verbally expressed, how the patient connects ideas (topic development), and whether he or she expresses paranoid or delusional ideas.

According to Andreasen (1979), the term thought disorder has been largely used in psychiatry to describe a gamut of different issues regarding human cognition, which ranges from the patient's capacity to abstract from external stimuli to how he or she organizes his or her utterances in a piece of discourse, by so communicating (in)coherently. Thus, the concept of thought disorder "is not a unitary construct, but rather encompasses several different components" (Berembaum and Barch, 1995: 350).

In an attempt to distinguish the various connotations of this term, a distinction between disorders in content and form was established. Broadly speaking, the former refers to what the patient talks about (Taylor, 1981), whereas the latter is concerned with the speed and with the forms of related links between ideas, i.e., how ideas are expressed. Despite these distinctions, psychopathologists have not established a common understanding of the different phenomena labeled under thought disorders; neither do they all consider the distinction between content and form a productive one.

The category of thought disorder has been under criticism for the past 30 years for various reasons. Andreasen (1979) pointed out that the current definitions of formal thought disorder in psychiatry are based on a close and mistaken correlation between speech and thought. Those who advocate for this correlation assume that thought might be assessed through speech, disregarding the complex cognitive processes that underlie linguistic behavior. Pinto and Ribeiro (2001) added that the concept of thought has not been uniformly defined. Most definitions presented in different manuals of psychopathology are tautological, circular, and imprecise, referring to vague notions such as 'ideas,' 'associations,' and 'symbols.' As Chaika (1990: 57) aptly stated, "thought remains an undefined entity. How then can we correlate speech with a concept so nebulous as thought?"

Andreasen suggested the term "disorganized speech" instead, as it translates what can indeed be observed, that is, the patient's speech. A list of operational and empirical categories deriving from clinical experience (such as derailment, poverty of content of speech, and tangentiality) describes the most frequent disorders. It distinguishes among the different facets of thought disorder and provides critical information about the relationship among specific symptoms (Andreasen, 1979). These categories represent a clinical assessment of thought, language, and communication disorders.

Until the 1970s, specific thought disorders, such as "looseness of association" (Bleuler, 1950), were

believed to be a pathognomic symptom (symptoms that are closely associated with a certain disorder or illness) of schizophrenia. That is, based entirely on this symptom, the clinician could develop a differential diagnosis between schizophrenics and bipolar patients (manic-depressives). However, in the past 30 years, studies have shown that this symptom "might as well occur in other diagnostic groups" (Andreasen, 1979: 1325), such as in patients with bipolar disorders. Thus, today the differential diagnosis between schizophrenia and mania is based on: (1) the course of action of the mental illness (i.e., its developmental traits) and (2) its prognosis. Experimental studies were carried out to investigate patterns of disorganized speech in psychotics by psychiatrists (Taylor *et al.*, 1994) and linguists (Chaika, 1990; Rochester and Martin, 1979). To control variables, these researchers employed structured instruments to trigger and elicit linguistic behavior that could function as evidence of pre-established categories. Rochester and Martin (1979) used summaries of short narratives to investigate types of failures in the speech of schizophrenic patients. Their problematic use of cohesive ties was seen as an indication of different types of thought disorders expected to occur in psychotic patients. Chaika (1990) made an analogous study of psychotic narration that does not support the view that psychotics do not use cohesive ties competently. More recently, research based on discourse analysis has examined data collected in natural settings, focusing mostly on psychiatric interviews (Ribeiro, 1994; Pinto, 2000). These studies have shifted the analysis to the coconstruction of doctor–patient communication, where meaning is conceived as jointly produced by both participants.

Coherence in Psychiatric Interviews: Topic, Schema, and Frame

"Using language involves doing several things at once, any one of which can go wrong" (Becker, 1982: 127): one speaks, composes words and structures, refers to the world, evokes prior texts, and relates to one's audience, all at the same time. When the integration is disrupted, an unsuccessful language and interactional experience results.

In analyzing doctor–patient interactions in psychiatry, certain concepts have proved useful. First, topic – what talk is about – requires a sense of being attuned to the message. Any encounter presupposes an understanding among participants regarding when and where to initiate talk, among whom, and by means of what topics (Goffman, 1982: 34). Additionally, participants must share rules for topic introduction and development. In this way, topics present boundaries that are marked either semantically or interactionally. "A single focus of thought and visual attention, and a single flow of talk, tends to be maintained and to be legitimated as officially representative of the encounter" (1982: 34). This understanding corroborates the participants' sense of coherence. In psychotic discourse, however, some of these expectations are not met.

Psychotic talk often presents a "loss of goal directedness" (Bleuler, 1950). The speaker ceases to contribute to the sequential (or cyclic) development of topics, thus thwarting topic continuity (Pinto, 2000). Referents may be introduced with no meaningful relationship to one another. Often, the speaker goes further and further off the track. Word associations tend to be governed by rhythmic relationships (sound play) rather than by semantic and pragmatic ties (Ribeiro, 1994). To complicate matters further, both doctor and patient fail to identify each other's topics. As a result, the process of topic negotiation often breaks down, few topics are expanded, and others are recycled with no preestablished agenda.

Topic provides a natural criterion for distinguishing instances of a speaker's deviant discourse from a discourse that matches our expectations about coherence (Ribeiro, 1994; Pinto, 2000). The complex step-by-step process of topic introduction and topic development reveals the amount of effort that participants must undertake in interaction to ensure topic continuity. When doctors face inconsistencies in the patient's discourse, they may use a number of strategies to keep the communicative channel open: they constantly summon the patient to the interview, they acknowledge the patient's statements, and they address some of his or her questions (Ribeiro, 1994). In doing so, doctors are constantly reassessing their assumptions about the patient's topic of talk.

How do topics relate to knowledge schemas? Knowledge schemas are cognitive entities consisting of "participants' expectations about people, objects, events and settings in the world" (Tannen and Wallat, 1993: 60). Schiffrin (1987: 12) pointed out that the concept of topic may help us "understand the role of shared knowledge in discourse," despite its inherent difficulties. This is particularly significant in instances of pathological discourse where social norms and linguistic rules are in many ways violated. For example, in an interview with the patient in a psychotic episode, discrepant knowledge schemas on the part of the doctor and patient may result in reciprocal distancing (Ribeiro, 1994). In each case, the speaker's topic selection follows divergent expectations regarding 'what this talk needs to be about.' Whereas the doctor proposes talk exclusively as 'interview talk,' the patient proposes talk as a 'family encounter.' He

or she may project an addressee (e.g., the father or mother), while the doctor remains mostly as an unratified participant (Goffman, 1982: 34). In this context, the patient introduces personal topics that belong to prior family schemas. Frequently, the referents lack specificity (i.e., they are encoded mostly by pronouns that presuppose a high degree of topic accessibility).

In standard psychiatric interviews – such as discharge interviews – background knowledge related to the immediate needs of the communicative context is mostly shared by patient and doctor. It orients topic selection by promoting certain topics and inhibiting others. The doctor controls content; thus, talk focuses on the development of 'official topics' (i.e., identifying the patient's name, age, marital status, assessing the patient's chief complaint, present illness, and past history). The patient's role is mostly confined to addressing the doctor's topics. A joint discourse results, where speaker's and listener's roles alternate following social and institutional norms. As a consequence, it is fairly simple to identify topics in the psychiatric interview because the doctor follows a standard agenda (Sullivan, 1970); furthermore, it is usually the same participant, the doctor, who initiates topics.

Whereas topics address the question 'What is talk about?' framing establishes a metamessage as 'how this talk must be understood.' Frames capture the dynamic way participants position themselves, relate to one another, and establish multiple contexts for talk. In Bateson's ([1972] 1981: 186) terms a frame "is (or delimits) a class or set of messages (or meaningful actions)." A metamessage (an implicit message) constitutes instructions to the listener on how to understand the messages within the frame. As people speak and perform actions, they signal to one another what they believe they are doing (i.e., what speech act(s) they are performing, what activity they are engaged in) and in what way their words and gestures are to be understood.

Frames are encoded and understood linguistically, paralinguistically (i.e., intonation, pitch, rhythm), and nonverbally. Topic is a key component in defining frames and part of the definition of an interactional situation. In clinical encounters, an institutional agenda often dictates topic selection. The doctor brings a topic agenda that helps establish the major interactional contexts (i.e., frames). In the psychiatric interview, the doctor plays a very active role in introducing topically relevant questions "to make sure that he knows what he is being told" (Sullivan, 1970: 21). Even such topical talk, however, can trigger more or less subtle frameshifting: a doctor's request for information about the patient's social history may trigger a personal story and thus a personal framing and a change in participation structure.

Table 1 Excerpt of an initial sequence of a psychiatric interview

Doctor:	What is your name?
Patient:	Joana Garcia.
Doctor:	And how old are you now?
Patient	Thirty-three.

The interrelation of frame and topic has implications for coherence (Ribeiro, 1994). Speakers and hearers have multiple options for coherence, as illustrated in Table 1.

Coherence is achieved within the exchange system as the doctor and the patient follow rules for turn-taking (A/B/A/B), while alternating the speaking role. It is achieved simultaneously in the action structure, when the patient provides the expected sequence (a request for information is followed by a statement). Finally, the propositional content coheres as participants jointly refer to the ongoing topic (i.e., name and age). To make sense of the above interaction, however, one needs to attend to the situation at hand. This is the opening of a standard medical (psychiatric) interview. For a psychiatric patient, making the proper choice from different linguistic and social options has definite implications for the doctor's evaluation and diagnosis. The patient must understand and jointly construct with the doctor the frames of the psychiatric interview. When both participants share an understanding of the ongoing talk, its purposes, and ways of interaction, coherence is achieved (Ribeiro, 1994).

Narrative and Topic Coherence

The psychiatric interview, modeled after the standard medical interview, follows a Question/Answer chain format, where the doctor requests information or clarification; frequently he or she probes further for more information and expands the topic. Such speech actions result in a Q/A/Q/A sequence that structures the interview mostly as an inquiry. There are many moments, however, when the patient introduces topics related to his or her illness and thereby begins a narrative, as shown in Table 2.

Whereas the doctor structures talk as inquiry, the patient views the encounter differently. She has stories (or a life story) to tell. "Patients view the medical encounter as an opportunity to account for their life and health stories in their own terms" (Ribeiro, 2002: 199).

In interviews with a patient in a psychotic episode, such as in the example above, narrative works to

Table 2 Example of a patient's lead into a narrative as a response to a Doctors question

Patient:	I work, I study, I take courses, I do things that are out of the ordinary, sometimes I did things out there that even people with a lot of courage wouldn't do . . . do, and that's why I'm taking medication here and I'm afraid
Doctor:	For instance, what types of things do you do?

describe the patient's personal topic agenda and its complex layering of references. Narrative analysis investigates ways that a story is told in bits and pieces and through multiple contextual embeddings. These bits of information may indicate to the psychiatrist relevant information about his patient's social and family history, present illness, and chief complaint. Listening to and understanding such stories are essential to the psychiatrist, who has the task of using patients' linguistic and nonlinguistic contributions as a source to assess their mental and psychological states.

Different frameworks for analyzing narratives are used in discourse studies in psychiatry. Labov's structural/functional framework – a narrative is "a method of recapitulating a past experience by matching a verbal sequence of clauses to the sequence of events which, we infer, actually occurred" (1972: 359–360) – has been used by researchers (Ribeiro, 2000) to analyze discourse cohesion and coherence. Labov's framework presents a schematic structure: stories would often have an abstract, an orientation(s), complicating actions, an evaluation(s), a coda, and a resolution. The evaluation component is considered most relevant as it is used by the narrator to indicate the point of the story: why it is being narrated. Also, temporal order constitutes the main thread of coherence. In psychiatric interviews, however, patients' stories are often presented in a quite fragmented form and do not adhere to the temporal order principle.

For example, Ribeiro (2000) described a particularly cohesive story ('the Bozo narrative') told by a patient in a fragmented but yet still coherent discourse. Following Labov's framework (1972), the narrator presents an abstract "I was married to Bozo, Bozo the clown." Several orientation parts follow: "Beto is the Bozo, he has been named 'Bozo the clown' by people at the hospital where he works as a physical therapist." In the complicating action, the patient informs that she "has been possessed by some Beto" and that they "have been fooling around." The notion of possession (of being possessed) implies lack of control (powerlessness) as well as irrationality – both social and cognitive traits related to mental illness. A narrative schema emerges for 'Bozo the clown' (a reference to Beto and to the patient herself), who shares attributes that play on ambiguity signaling both euphoria (laugher and fun) and depression (sadness). This oscillating mood and related references are particularly interesting since the patient has a manic-depressive (bipolar) disorder.

Other research frameworks – that highlight narrative as a genre and the process of narration (Linde, 1993; Mishler, 1986) – provide ways of listening to (and analyzing) stories in clinical and research interviews. Such frameworks investigate how individuals share experiences through the telling of life stories. It also focuses on the coconstruction of participants' social and conversational identities. Storytelling is viewed as a situated discursive practice, as a way to project who we are to our addressee, according to our communicative purposes for that specific interaction. In this process, the narrator uses a wide range of linguistic forms to express purpose and intentionality. Coherence emerges from the joint construction of meaning by the participants. It is not "an absolute property of a disembodied, unsituated text" (Linde, 1993: 12).

Mishler (in press) added that narration time is not solely chronological; rather, people interpret activities according to the way they are experienced and narrated. This understanding subscribes to the relational concept of identity: human beings experience who they are along a continuum of tensions and contradictions in the many social worlds they live in. They are not progressive nor coherent. The interpretation of past events is achieved in light of how they are conceived in the very moment of narration, that is, as the story unfolds for that specific audience in a specific context. Accordingly, unfolding stories in psychiatric interviews must also be considered as situated discursive practices and viewed as context specific.

Psychiatry relies on clinical practice where the patient's sociolinguistic competence is being assessed. A successful assessment of the patient's mental state requires that the patient address the institutional topics of the psychiatric interview. Whereas some interactional processes may facilitate communication, others may inhibit it. Open-ended questions, for example, allow for the production of more spontaneous and lengthy responses, where stories may then emerge. And probing questions about the details of a narrative, for instance, might reveal specific information that would otherwise not be evaluated. Thus, the unfolding of a narrative in an interview situation constitutes an important tool for gathering relevant information so that the doctor may successfully reach a diagnosis. Moreover, listening to stories in an interview situation strongly enhances involvement between the doctor and the patient.

Medical Discourse: Sociohistorical Construction

B-L Gunnarsson, Uppsala University, Uppsala, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Scientific language and discourse emerge in a cooperative and competitive struggle among scientists to create the knowledge base of their field, to establish themselves in relation to other scientists and to other professional groups, and to gain influence and control over political and socioeconomic means. In every strand of human communication, language and discourse play a role in the formation of a social and societal reality and identity. This is also true both of the formation of the different professional and vocational cultures within working and public life and of the formation of different academic cultures.

Historically, language has played a central role in the creation of different professions and academic disciplines, and it continues to play an important role in the development and maintenance of professional and institutional cultures and identities. Societal, social, and cognitive factors all make important contributions to the construction of professional cultures. Professionals try to create a space for their field within society. They try to establish themselves in contact and competition with others within their group as well as with other groups. Their knowledge base and its linguistic forms are created in a societal and social framework.

Diachronic Studies on the Development of Scientific Genres

A constructionist perspective on the emergence of scientific discourse and text genres is found in various traditions. Within the tradition of sociology of science, several studies have been devoted to analyzing the role of texts in the establishing of scientific fact. The scientific field is seen as a workplace, a laboratory, where social rules determine the establishing of facts and the rank order of the scientists. Knorr-Cetina (1981) was one of the first to describe the writing up of results as a process of tinkering with facts rather than a knowledge-guided search. Latour

and Woolgar (1986) described the social construction of scientific facts as an antagonistic struggle among scientists, leading to a purposeful diminishing of the results of others and a leveling up – to a generalized level – of one's own results.

Bazerman (1988) studied the rise of modern forms of scientific communication, focusing on the historical emergence of the experimental article. A social-constructivist approach in relation to written texts is also found in Bazerman and Paradis (1991), which examined the important role played by texts in profession building. Textual forms and definitions are found to impose structure on human activity and help shape versions of reality. Texts are shown to play powerful roles in staging the daily actions of individuals, and to be important factors in the rise of action. In Gunnarsson *et al.* (1997), which examined both professional written communication and spoken interaction, the central theoretical issue is how language, written genres, and spoken discourse are constructed as successive and continuous interplay between language and social realities. A sociorhetorical perspective on the scientific genre is also developed in Bhatia (1987), Swales (1990), MacDonald (1994), and Berkenkotter and Huckin (1995). The emergence of the English scientific text genres has been analyzed in several important works, including Atkinson (1999) and Valle (1999). Extensive studies have also been made into scientific written communication in other languages, e.g., German (Standard German) (Schröder, 1991) and Swedish (Gunnarsson, 1997, 1998, 2001a; Melander, 1991, Näslund, 1991). The differences between academic genres developed within different national cultures have also been analyzed from a socioconstructivist approach, e.g., Mauranen (1993).

The Construction of Professional Discourse

In this article an exemplary picture of the emergence and development of medical written discourse will be sketched. In order to understand the historical development of professional medical language and communication in its rich and varied totality, we must study the dynamic processes behind the construction of medical language.

In this dynamic process, three main layers are distinguished: one relating to **cognitive** types of activities, one to **social**, and one to **macrosocial** or **societal**. Professional culture is built up via these layers, which means that all three must be considered in order to get a full picture. Written texts as well as spoken discourse are constructed as cognitive, social, and societal activities within the different professions and branches of working life. (The term 'profession' is here used in quite a general sense, including academic as well as nonacademic discourse.)

If we begin by considering the **cognitive layer**, we find that each profession has a certain way of viewing reality, a certain way of highlighting different aspects of the world around it. Socialization into a profession means learning how to discern the relevant facts, how to view the relations between different factors. We are taught how to construct and use a grid or a lens to view reality in a professionally relevant way. Language, texts, and spoken discourse help us in this construction process. We use language in the construction of professional knowledge. Medical terminology, medical text patterns, and medical text and discourse content have developed as a means of dealing with reality in a way that is appropriate for medical purposes.

The way in which language is used is related to existing knowledge within the field and also with conceptions about what constitutes knowledge and the attitude that should be adopted to it. What is therefore important is what scientists consider they know about different sectors of reality at different periods, what knowledge they believe is relevant in this field, and how they consider data should be collected, observed, and analyzed. Attitudes and norms regarding what is professionally relevant and right are thus built into the cognitive structure.

The knowledge base of a field has a network of relations with other fields. The cognitive structure of a professional language thus reveals its dependence on and relationship toward other knowledge domains, and this knowledge-based network can vary over time. In metaphors, in terminology, in modes of reasoning, and in diagrams, the contribution of adjacent fields to the construction of professional knowledge is revealed. For example, many fields owe a debt to statistics, psychology, mathematics, sociology, physics, economics, politics, and religion, and this debt can be seen in the language that is used.

Second, regarding the **social layer**, every professional group, like other social groups, is also formed by the establishment of an internal role structure, group identity, group attitudes, and group norms. The need for a professional identity, for a professional sense of 'us-ness,' for separation from the out-group, has of course played an important role in the construction of professional group language and constantly motivates people to adapt and be socialized into professional group behavior. Socialization into a group also means establishing distance from people outside the group.

The use of medical scientific language during different periods is thus related to the type and level of the scientific community (the social group), its size, structure, degree of professionalization, degree of internationalization, degree and nature of mutual contacts, existence of publications, etc.

Third, as regards the **macrosocial** or **societal layer**, each professional group also stands in a particular relationship to the society in which it operates; it exerts certain functions and is given a certain place within that society. The members of a profession play a role in relation to other actors in society, and the professional group acts in relation to other groups. They play – or do not play – a role on the political scene, within the business world, the education system, in relation to the media, etc. And this cluster of societal functions is essential for language. It is through language that professional groups exert their societal function. If they are going to play a role on the political scene, they have to construct their communicative behavior in a way that is adequate for that purpose. Their relationship to written texts and spoken discourse and to different genres is also important. Professionals adapt to established genres, but are also involved in forming new genres.

The way in which language is used within science during different periods is linked with the relationship of the scientist and the scientific community to society in general. Factors that are important are the status of the profession and its role in society, both the status of the scientific community and to what degree and in what way it is integrated into society. The societal layer is thus related to economic and political factors. It is related to power and status patterns in the particular society, i.e., the nation-state, as well as on the global scene.

The three layers are strongly related to the emergence and continuous recreation of professional language, and they constitute a part of the construction of professional language and discourse. Historically, language is constructed in relation to all these layers. The cognitive establishment of the field takes place at the same time as the professions fight for their place in society and for the strengthening of their group in relation to other groups.

Stages in the Development of Medical Science

Medical knowledge and practice took a great step forward in the 17th and in particular in the 18th century. However, it was only gradually that it developed into a science in the modern sense. Since the 18th century, all societies have undergone radical change. Changes have also taken place within the medical scientific community:

1. Medical knowledge has grown immensely.
2. Science in general and the philosophy of science have undergone changes. Statistics and empirical methods have developed. Positivism has become the only accepted view in many sciences.
3. The medical profession has gradually become increasingly established and recognized. Today, doctors are considered highly valuable professionals, and medical scientists and medical research are considered highly important to society.
4. The medical scientific community has become much larger. The number of doctors, medical scientists and students of medicine has increased, as has the number of medical journals and conferences.

Important changes have thus taken place relating to medical science, science in general, the medical profession, and the medical-scientific community. This article will explore how language and discourse are essential elements in the construction of science, in profession building and in the shaping of the scientific community, and that academic genres play important roles in this process of constructing scientific knowledge and the role of the scientist in society, and in the growth and strengthening of the social network among scientists.

Changes as to language and text patterns will be discussed in relation to three scientific stages: the pre-establishment stage, the establishing stage, and the specialized stage. For each layer the three stages can be summarized on a developmental axis:

Cognitive layer:
- Individual findings – Accumulation of findings – Integration into theory

Social layer:
- Isolated researchers – Academic grouping – Advanced scientific community

Macrosocial/societal layer:
- Scientists function within society – Scientists function within society and academic groupings – Scientists function with the scientific community.

Scientificality in Swedish Medical Articles 1730–1985

The empirical results referred to are based on studies on Swedish medical language carried out at Uppsala University. The whole corpus analyzed comprises a total of 360 scientific and popular articles from three fields – economics, technology and medicine – and six periods (Gunnarsson, 1998). The medical

subcorpus which will be focused on here consists of 60 scientific articles, 10 from each of the six periods 1730–1799, 1800–1849, 1850–1880, 1895–1905, 1935–1945, and 1975–1985. All these articles come from scientific journals and deal with pulmonary diseases (30 articles) or skin diseases (30 articles). Our analyses have focused on four text linguistic levels: the cognitive, the pragmatic, the macrothematic and the microsemantic. We have also made analyses relating to the vocabulary and terminology (Gunnarsson, 1998).

Content and Content Structuring of the Texts

The content and content structuring of medical articles will be related to the stage reached by the domain of medical science, in terms of degree and type of scientificality, and also the role of scientists in society.

The cognitive analysis examines the content of the text in relation to five 'cognitive worlds': a scientific world, a practical world, an object world, a private world, and an external world (cf. Gunnarsson, 1992). Within each of these, two or three aspects were discerned:

World	**Aspect**
Scientific	Theory
	Classification
	Experiment
Practical	Work
	Interaction
Object	Phenomenon-focused
	Part-focused
	Whole-focused
Private	Experience
	Conditions
External	Conditions
	Measures

Each proposition in the articles was categorized in relation to **world** and **aspect**. We could thus calculate the proportions of the total number of propositions representing each world and each aspect in texts from different periods.

The analysis showed a very clear increase in the proportion of each text devoted to the scientific world, that is, to the presentation of 'theory,' 'classifications,' and 'experiment,' over the periods. On the other hand, there was a clear decrease in the role of the external world in particular, that is in the proportions of texts dealing with 'conditions' and 'measures' of a political, economic, and social nature. There was also an increase in the proportion of 'experiment/observation' within the scientific world and a decrease in the proportion of 'measures' within the external world.

The cognitive analysis also comprised an analysis of text content in relation to four time **dimensions**, 'cause,' 'phenomenon,' 'process,' and 'result,' which showed that the proportions of each text devoted to describing 'causes' and 'phenomena' have decreased over time, while the proportions devoted to 'processes' and 'results' have increased.

Another analysis focused on the macrothematic structure. The content of the medical articles was categorized in relation to four **superthemes**, 'introduction,' 'theme development,' 'discussion,' and 'conclusions.' This analysis revealed an increase as regards how much of each text is devoted to the superthemes 'introduction' and 'theme development' (that is, to a description of materials, methods, results). The proportion devoted to 'discussion' and in particular to 'conclusions,' on the other hand, had decreased.

A third analysis, which aimed at a description of the pragmatic character of the texts, e.g., the types of **illocution** present, pointed to an increase as regards 'informative' and 'explicative' illocutions and a decrease in 'expressive,' 'argumentative,' and 'directive' illocutions.

To sum up, the changes in the content and content structuring of Swedish medical articles from 1730 to 1985 show the following tendencies: more 'scientific world,' less 'external world'; more 'experiment,' fewer social, political, and economic 'measures'; more 'process' and 'results,' less 'cause' and 'phenomenon'; larger proportion of 'theme development,' smaller proportion of 'discussion' and 'conclusions'; more 'informative' and 'explicative' illocutions, fewer 'expressive' and 'directive' illocutions.

These findings relating to changes in the medical article genre point for one thing to a development of medical science. The knowledge structure of the texts appears to have changed, to include more emphasis on experiment and on process and results. There is also a trend toward a genre of a more purely descriptive character, in which the main part of the text is devoted to developing the theme, that is, to a description of the experiment, observations, etc. These are features which could be related to a positivist scientific ideal. All these results can be related to the cognitive layer of the construction of academic discourse.

These results also reveal the role played by scientists in society. In terms of text content, the proportion devoted to the external world and external measures has decreased, as has the proportion devoted to conclusions and directives. Such results can be discussed in light of the specialization and professionalization of society. Compared with earlier periods, scientists today act to a greater extent in a

discourse community of their own. Science in general and medical science in particular is accepted and highly esteemed in modern society. Considerable funding is given to medical research. The role of large-scale experiments has increased.

The discourse changes can be related to this endeavor among medical scientists to become specialists, and a profession of their own, with their own exclusive domain to deal with. A high degree of scientificality in spoken and written discourse provides prestige.

A more purely scientific genre has emerged. Scientist-writers have turned toward their own group, and the medical article genre has become a within-science genre. The popularization of medical findings is taken care of by others – trained journalists. Scientists can write for their own group, and do not have to bother about a growing distance between the lay public and the experts. The article genre has become more exclusively internal, and less concerned with reaching out to other sectors of society.

These results can also be interpreted in light of the interplay between the cognitive and societal layers. The role played by the medical profession in society interrelates with the presentation of scientific content.

Formal Organization of the Text

The formal organization of the texts and their rhetorical patterns will be related to the stage reached in the development of the medical scientific community. A strong scientific community reveals itself in firm genre conventions, that is, in more homogeneous texts, and also in explicit markings of belonging to a group.

The number and types of headings in the modern Swedish articles vary over time. The use of section headings has increased dramatically. Also the type of heading has changed. In the early periods, headings relate to the content of the article, while in the modern article they relate to its structure: 'Material,' 'Methods,' 'Results,' 'Discussion,' 'Conclusions.' The modern headings thus structure the presentation in a general scientific way, which also reflects a more homogeneous organization of the texts.

An increasing homogeneity is also found in relation to the thematic article structure (Gunnarsson, 1993). The articles from the period around 1980 (1975–1985) were clearly more homogeneous in terms of their linear text structure than earlier articles. Also the introductions in articles from different periods revealed a gradually greater homogeneity. This homogeneity can also be seen in a contrastive perspective; that is, the Swedish pattern has come to resemble that of the English scientific article, as described in Swales (1990).

Another finding relates to the information flow of the text. An analysis of the connection between content structure and graphical disposition in articles from different periods showed that each sentence has become more independent with regard to the surrounding text. It introduces a new angle, which means that it becomes less integrated with its neighboring sentences (Melander, 1993). We thus find a change toward a fact-listing or 'catalogue' style in the modern article.

This tendency toward a catalogue style can be seen as another feature reflecting firmer genre conventions. When texts are organized in a homogeneous and predictable way, there is less need to elaborate on the details. Readers know where in the text they will find different types of content. The tendency toward a more catalogue-like article could also be seen as indicating a strengthening of the scientific community. The knowledge of this community is well established among the specialist readers, and need not be elaborated on.

Other analyses reveal that the number of references per article has increased over time, and that the way of presenting them has become more homogeneous. Another tendency relates to the changed use of personal pronouns. In the articles from the 18th century, the pronoun 'I' was quite a frequent word, while it has more or less totally disappeared in the articles from the latter part of the 20th century. The pronoun 'we,' on the other hand, which was quite unusual during the first two periods, has since the middle of the 19th century had a similar rank. The author's explicit marking of article relevance has also changed over time. Here we find a shift from a societal orientation in earlier periods to a more internal orientation in the last period (Gunnarsson, 1998).

To sum up, the changes as to the formal text organization and the rhetorical patterns show the following diachronic tendencies: more headings; more homogeneous text organization; more homogeneous article introductions; more fact listing; more references; less use of the personal pronoun 'I'; more relevance marking relating to the 'group.'

The medical article has developed toward greater homogeneity – relating to the use of headings, the superthematic text structure, the rhetorical structure of introductions, etc. – which indicates a strengthening of genre conventions. The medical article has become more established as a genre, and its genre conventions have become firmer and thus more homogeneous. This strengthening of the academic article genre, however, is also a sign of a growing and stronger medical discourse community. For the

medical discourse community, as for most scientific discourse communities, writing plays an essential role as a group marker, and the establishing of firmer conventions for written text genres is part of the growth and strengthening of this community. The trend toward a more fact-listing and catalogue type of article can also be seen as a sign of a stronger discourse community, in the sense of being more homogeneous and closed. It is a well-known fact within sociolinguistics that communication within a dense group or network needs to be less explicit and elaborated than communication within one more open and less dense.

The modern habit of giving references to the works of colleagues is another sign of a strong discourse community, a discourse community with a clear group feeling. When the group is essential to its members, it becomes important to indicate one's sense of belonging and one's relationship to other group members. Problems relating to the group also become more important than those relating to the world outside the group. The modern tendency to list references, to use 'we' instead of 'I,' and to mark relevance in relation to one's own group can be viewed from this social perspective. I would suggest that these text features are part of the construction of an increasingly close-knit (dense) medical discourse community.

There is also a connection between these features and the role of medical scientists in society; that is to say, the strengthening of the professional group is paralleled by a process of gradual specialization of the professions. These features are thus also part of the construction of a role for the medical community within society. We can thus see how the social and societal layers interact. Strengthening of the internal group structure is interrelated with the underlining of a role for the group in society.

Linguistic Expressions of Evaluations

The linguistic expressions of evaluation and its variation over time will be related to the positioning of the scientist/author on the developmental axes for the three contextual dimensions. The study referred to was based on an analysis of 30 Swedish scientific medical articles from six periods. All the articles dealt with pulmonary diseases. The study, which comprised an analysis of evaluations linked to descriptions of the subjects studied, the diseases and treatments, the introduction of the author's own initiatives, and descriptions of the research and findings of others, focused on three main aspects: (1) what is being evaluated, (2) through whom the evaluation is taking place, and (3) how the evaluation is being made (Gunnarsson, 2001a).

In articles from all the periods, the object of the study and the initiatives of other researchers were evaluated. The author also referred to his own initiatives in most articles. From a diachronic perspective, however, it is more interesting to consider the second aspect; that is, through whom the evaluation is taking place (author's own voice, author through others, author through facts). A comparison of the medical texts from the 18th, 19th, and 20th centuries shows that in the earliest texts the evaluation is made by the author himself, using his own voice, whereas in later articles it is allowed to emerge indirectly via facts from others, e.g., in references to the other articles.

A change over time is also found in relation to the third aspect, how the evaluation is being made. When articles from the 18th century are compared to articles from the 20th century, we find a weakening tendency; that is, the evaluations in articles from 1730 are expressed in a more severe way. A more obvious change, however, relates to the degree of certainty. Here we find a discernible increase in the use of hedges and other expressions of caution over time (cf. Salager-Meyer, 1994).

We thus find a progressive moderation of the author's own voice in the medical articles; in other words, increasingly the focus is placed on facts. There is another clear change in the author's relationship to facts, which is revealed in an increase in the frequency of markers of epistemic modality.

These tendencies were also found in analysis of word frequencies. As mentioned earlier, there is a change in the use of the personal pronouns *jag* 'I' and *vi* 'we' in the articles over time. The occurrences of the pronoun *jag* are reduced by half between the first period (18th century) and the fourth period (1895–1905) and disappear completely during the sixth period (1975–1985). To some extent the pronoun 'I' is replaced by the pronoun 'we.' In this case, however, the increased use of 'we' is mainly explained neither by the use of reader-inclusive 'we' nor by co-authorship. It could rather be linked to the progressive phasing out of authorial identity in scientific prose.

A comparison of the frequencies of a number of markers of modality in the Swedish medical corpus revealed an increase over time. All nine markers – *torde* 'is probably,' *tyder* 'suggests,' *tycks* 'seems,' *tänkbar* 'conceivable,' *tveksam* 'doubtful,' *sannolik* 'likely,' *sannolikhet* 'likelihood,' *möjlig* 'possible,' *möjlighet* 'possibility' – revealed a linear increase in frequency over the six periods. This increasing tendency to be cautious can of course be seen as a sign of the progressive extension of medical knowledge; that is, it can be related to the author's placement on the knowledge axis. The greater the body of collective

Table 1 Text and context during three centuries

Dimension	*1700:1*	*1800:2*	*1900:3*
Cognitive	Individual findings	Accumulation of findings	Theoretical integration
Social	Isolated researchers community	Academic groupings	Developed scientific
Macrosocial	Scientists act within society	Scientists act within society and academic groupings	Scientists act within the scientific community

knowledge, the more aware authors are of its relativity. But it could also be linked to circumstances within the social group, in this case the medical community. In order to survive in a competitive society, which is what the world of medical research undeniably is, one must be careful not to lose face, and take care not to threaten the face of others. Ideas of this kind are proposed in Myers (1989). Myers claims that in order to survive in the competitive academic world, modern scientists adopt pragmatic politeness strategies, and that Brown and Levinson's concepts of 'face saving' and 'face threatening' are also relevant in the analysis of scientific texts (Brown and Levinson, 1987). Scientists tread a narrow path between the need to emphasize their own achievements on the one hand and to criticize those of their peers on the other.

It may well be that the difference in the wording results from the increased knowledge scientists now possess about illnesses and their treatment, i.e., that the difference can be linked to the cognitive dimension. Or it may result from greater awareness of the importance of politeness in a large and well-developed scientific community, i.e., the difference can be linked to the social dimension; doctors/researchers admittedly make evaluations, but they avoid expressing them subjectively and straightforwardly and choose greater objectiveness, thus showing more caution.

Lastly, the variation in linguistic expressions of evaluations will be systematically related to the three scientific stages and the three layers distinguished earlier, and articles from the 18th, 19th, and 20th centuries will be placed on developmental axes. illustrates the relationship between text and context for medical scientific articles during three centuries.

In the articles from the 18th century, we encounter a number of different individuals – the author himself, his colleagues, and his patients – and their experiences and judgments are described. The typical article is full of explicit, severe, and assured evaluations which concern the object of the study – the illness and method – and also the advocates of the method, its naïve practitioners. In the way the author writes, he places himself fairly obviously toward the left of all three contextual axes in Table 1; he treats individual findings as if they exist *per se*, he describes himself and his colleagues as isolated researchers and he seems to act within society rather than the scientific community.

In the articles from the 19th century, the typical author adopts a considerably more analytical attitude to the research of others. The author himself figures as an evaluator. He also explicitly adduces the opinions of other researchers. The evaluations are of medium severity and the author marks his doubts in different ways. The author is fair and square in the middle of the contextual axes.

In the articles from the 20th century (around 1980), the typical author does not express himself in his own voice or explicitly through others. Evaluations take the form of the presentation of facts, supported by references to other works. Summaries of the research of others form an integral part of the description of the illness/method. What characterizes this and other articles in the subcorpus from this period is above all the attitude adopted to facts. The evaluations are not few in number, but they are weak to medium, severe rather than severe, and they are presented throughout as less certain – in other words these authors should be placed to the right on the contextual axes.

Conclusions

Language constructs science in relation to the cognitive layer (the scientific content), the societal layer (scientists' role in society), and the social layer (relations within the group). This construction process has been in progress since the first doctors tried to establish themselves as medical scientists and it is still continuing. In Sweden this process began in the 17th century. However, it was not until the middle of the 18th century that Sweden became a national writing community. Before 1740, the language of the learned was Latin, but in the Era of Liberty, from the middle of the 18th century, Swedish was gradually accepted as a scientific language, and the construction of medical science and the medical scientific community was related over a long period

to the development of the Swedish medical article as a genre. This article has focused on this phase in the Swedish medical history, an account which ended in 1985.

What has taken place since then is an accelerating Anglicization of the academic writing community in Sweden. English is now used in medicine as the medium for Ph.D. theses, for conference abstracts and papers, and for articles presenting original research (Gunnarsson, 2001b). *Läkartidningen*, the Swedish medical journal, still exists, but is no longer the prime forum for presentations of new findings. The Swedish medical scientists of today choose to present their research in English in international medical journals. When they write in *Läkartidningen*, they do so with other purposes than to present original research findings. The Swedish medical scientific community has thus turned diglossic; that is, English is used for certain purposes and Swedish for others. In the Swedish medical journal, articles give overviews and present research relating to basic diseases, but this is no longer a journal for the first presentation of new research (Gunnarsson *et al.*, 1995).

A development of the kind here described is not country specific. The shift from Latin to the national language took place around the same time in most Western countries, and the modern spread of English as a scientific language is universal (Ammon, 2001). The Anglicization of the medical scientific community and the accelerating use of the Internet as a communicative tool has lead to an intensified globalization and also homogenization of science and scientific language. From a sociohistorical perspective this development is most interesting and in the future will certainly lead to important investigations.

Introduction

Since the inception of serious scientific publication in 1665, there has been a continued attempt to improve both the content and the presentation of articles. The peer review process (which dates back only to World War II and has been adopted by over two-thirds of biomedical journals) and the adoption of the IMRAD pattern (Introduction, Materials and Methods, Results, and Conclusion) in the late 1960s represent two such attempts. Numerous voices have been raised lately, however, against the peer review process and the IMRAD formula. Peer review indeed carries the recognized danger of delay, bias, and expense, yet it remains the best method of evaluating scientific work thus far and it has survived for over 300 years (Lock, 1988). As regards the IMRAD pattern, it has been named a straightjacket around the author, thus impeding creativity and personality. Yet the IMRAD pattern allows readers to answer the fundamental questions.

In the 1960s, the *Journal of the American Medical Association* took an innovative step toward improving biomedical communication by moving the summary and conclusions of articles to the beginning. The *Canadian Medical Association Journal* also adopted this abstract format. The latest major development involving abstracts in the late 1980s was the introduction of the so-called structured abstract, currently required for all medical papers reporting clinical trials. This concept has been worked out by a McMaster University team and the *Annals of Internal Medicine*. What is the motivation that lies behind such an initiative?

The Pivotal Role of Abstracts

No experienced editor believes that readers of his or her journal go through each issue article by article, word by word. Some readers probably scan the tables of contents, decide which articles, if any, merit their further attention, and scan the titles and abstracts of selected papers. Abstracts of research articles are indeed by far the most widely read parts of scientific papers. Much of the time, it is the only part that is read. According to Stephen Lock (1988), former editor of the *British Medical Journal*, in practice, most readers of scientific papers are content to read the paper's title and abstract, casting an eye over the remaining sections. The ubiquitous availability and widespread use of on-line literature search mechanisms, which provide an often untruncated abstract, have done nothing but increase this likelihood. The abstract, then, has a pivotal role not only in answering the fundamental questions readers ask themselves when reading a scientific article (What is the study's objective? What is the method used? What are the results obtained? And what are the conclusions reached?), but also in being able to stand on its own as a packet of information. As argued before, this latter function is all the more important now because many online databases and medical journals do not provide the full articles (unless one pays for them) but only the title, the authors' names, some bibliographical details, and the abstract. In view of its importance, then, the accuracy of information provided by the abstract is critical.

Some of the abstracts that accompany medical papers are adequate for these purposes, but many are not. In her study on the structure of medical abstracts, for example, Salager-Meyer (1990) found

Introduction

Since the inception of serious scientific publication in 1665, there has been a continued attempt to improve both the content and the presentation of articles. The peer review process (which dates back only to World War II and has been adopted by over two-thirds of biomedical journals) and the adoption of the IMRAD pattern (Introduction, Materials and Methods, Results, and Conclusion) in the late 1960s represent two such attempts. Numerous voices have been raised lately, however, against the peer review process and the IMRAD formula. Peer review indeed carries the recognized danger of delay, bias, and expense, yet it remains the best method of evaluating scientific work thus far and it has survived for over 300 years (Lock, 1988). As regards the IMRAD pattern, it has been named a straightjacket around the author, thus impeding creativity and personality. Yet the IMRAD pattern allows readers to answer the fundamental questions.

In the 1960s, the *Journal of the American Medical Association* took an innovative step toward improving biomedical communication by moving the summary and conclusions of articles to the beginning. The *Canadian Medical Association Journal* also adopted this abstract format. The latest major development involving abstracts in the late 1980s was the introduction of the so-called structured abstract, currently required for all medical papers reporting clinical trials. This concept has been worked out by a McMaster University team and the *Annals of Internal Medicine*. What is the motivation that lies behind such an initiative?

The Pivotal Role of Abstracts

No experienced editor believes that readers of his or her journal go through each issue article by article, word by word. Some readers probably scan the tables of contents, decide which articles, if any, merit their further attention, and scan the titles and abstracts of selected papers. Abstracts of research articles are indeed by far the most widely read parts of scientific papers. Much of the time, it is the only part that is read. According to Stephen Lock (1988), former editor of the *British Medical Journal*, in practice, most readers of scientific papers are content to read the paper's title and abstract, casting an eye over the remaining sections. The ubiquitous availability and widespread use of on-line literature search mechanisms, which provide an often untruncated abstract, have done nothing but increase this likelihood. The abstract, then, has a pivotal role not only in answering the fundamental questions readers ask themselves when reading a scientific article (What is the study's objective? What is the method used? What are the results obtained? And what are the conclusions reached?), but also in being able to stand on its own as a packet of information. As argued before, this latter function is all the more important now because many online databases and medical journals do not provide the full articles (unless one pays for them) but only the title, the authors' names, some bibliographical details, and the abstract. In view of its importance, then, the accuracy of information provided by the abstract is critical.

Some of the abstracts that accompany medical papers are adequate for these purposes, but many are not. In her study on the structure of medical abstracts, for example, Salager-Meyer (1990) found

that 48% of them were poorly structured. Poorly structured abstracts were defined as those that did not follow the structural guidelines for abstract writing indicated in the journal's Instructions for Authors/Contributors. Among the most frequent structural flaws that Salager-Meyer and her specialist informants identified were as follows: (1) lack of a fundamental move (e.g., the objective, the methods, the results, or the conclusions of the study); (2) conceptual overlapping (e.g., presentation of partial results, statement of methods, and presentation of some more results); (3) lack of two fundamental moves (e.g., the objective or the conclusions of the study); and (4) illogical structuring (e.g., the methods move precedes the statement of purpose, or the objective of the research is presented after the results move).

Using objective criteria, other investigators (Narine *et al.*, 1991) assessed the quality of traditional or conventional abstracts of the 33 original research articles published in the *Canadian Medical Association Journal* in 1989. The mean overall score was 0.63 out of 1. Abstracts were found to be deficient in the reporting of technical descriptors of study design, study variables, and subject selection. Results were often reported without supporting data and many abstracts failed to address study limitations and recommendations for future study. This is how the concept of 'structured abstract' arose.

Definition and Objective of a Structured Abstract

The idea of a structured abstract, i.e., an abstract that describes a study using specified content headings rather than pure paragraph format, was suggested by the *Ad Hoc* Working Group for Critical Appraisal of the Medical Literature in 1987 to provide more information for articles reporting original research of medical care, to help health professionals to quickly assess the reliability and content of a clinical report, to facilitate peer review, and to aid accurate indexing and retrieval of reports from computerized databases such as MEDLINE and EMBASE.

Structured Abstract of Clinical Trials

Such abstracts concisely report key aspects of the purpose, methods, and results of a trial in a consistent way and using a standard glossary of terms (e.g., cohort, cost–benefit analysis, randomized). The structured abstract for clinical trials should mention seven key aspects by means of requisite content headings. We thus have a seven-part tabular format such as:

1. *Objective*: states the question(s) addressed in the paper;
2. *Design*: indicates the basic design of the study (blind, double-blind, randomized, cross-over, etc.);
3. *Setting*: mentions the place where the research was carried out;
4. *Patients or participants*: indicates the number of patients who were enrolled in the study, how they were selected, and how they were distributed per group;
5. *Main outcome measures*: explains the treatment and its administration route;
6. *Results*: mentions the study end-points;
7. *Conclusions*: refers to the main conclusions, including direct clinical applications.

Some medical journals, though, such as the *Lancet*, accept a four-part tabular format, but each 'move' is always clearly preceded by an explicit heading:

Background (30 words). A summary of the general topic and the purpose or hypotheses of the study.

Methods (50 words). A description of the materials (generic names of drugs and equipment should be used, unless the particular brands are crucial to the study), the methods (including the type of study design), and the subjects (important eligibility criteria, number, and selection process).

Results (100 words). A statement of the primary results of the study; the types of analysis used should be indicated, as should levels of statistical significance and confidence intervals.

Conclusions (30 words). A statement of the conclusions (the answers to the hypotheses posed at the beginning of the study). Only the conclusions that are directly supported by the evidence provided by the study should be included. Any need for further study should be indicated.

Clinical Implications (30 words). A description of what the conclusions imply for clinical practice.

Rapid adoption of structured abstracts by journals resulted in an annual doubling of reports with structured abstracts published from 1989 through 1991 appearing in MEDLINE; 15% of these were reports of clinical trials.

Structured Abstract of Review Articles

Mulrow *et al.* (1988) also proposed standardized guidelines for informative review abstracts, i.e., abstracts of review papers. The proposed structure is the following:

1. *Context* or *background*: brief statement of the state-of-the-art;
2. *Objective*: the primary objective of the review article;
3. *Data sources*: a succinct summary of data sources;

4. *Study selection and data extraction*: the number of studies selected for review, how they were selected, the type of guidelines used for extracting data, and how they were applied;
5. *Data synthesis*: the methods of data synthesis and key results;
6. *Conclusions*: key conclusions, including potential applications and research needs.

The following excerpts are taken from Mulrow's *et al.*'s (1988) paper. They give an example of an original (unstructured) abstract and of its structured equivalent:

Original Abstract

Use of digitalis for the treatment of patients with congestive heart failure and sinus rhythm remains controversial. To ascertain the proper therapeutic role of digitalis, we have critically appraised the published clinical evidence of digitalis efficacy using standardized methodologic criteria. A search of the English literature between 1960 and 1982 identified 736 articles, of which 16 specifically addressed the clinical evaluation of digitalis therapy for patients with congestive heart failure and sinus rhythm. Only two double-blind, placebo-controlled trials provided clinically useful information. One study showed that digoxin therapy could be withdrawn successfully in elderly patients with stable congestive heart failure. The other showed that patients with chronic heart failure and an S3 gallop benefited from digoxin therapy.

Structured Abstract

Purpose: To ascertain the clinical benefits of digitalis treatment in patients with chronic congestive heart failure and sinus rhythm.

Data Identification: An English-language literature search using MEDLINE (1966–1982), Index Medicus (1960–1965), and bibliographic reviews of textbooks and review articles.

Study selection: After independent review by three observers, 16 out of 736 originally identified articles were selected that specifically addressed the stated purpose.

Data extraction: Three observers independently assessed studies using explicit methodologic criteria the quality of evaluating clinical trials.

Results of data synthesis: Because of deficient selection criteria and study methods in 14 studies, therapeutic efficacy could not be adequately assessed. Two randomized, double-blind, placebo-controlled studies suggested that digitalis could be successfully withdrawn from elderly patients with stable heart failure, whereas patients with an S3 gallop might benefit from digitalis.

Conclusions: The benefits of digitalis treatment for patients with congestive heart failure and sinus rhythm are not well established. To better delineate the therapeutic benefits of digitalis, investigators must conduct more rigorously designed trials involving patients with newly diagnosed failure and varying degrees of failure.

As can be seen from the examples provided, the differences in information and organization between the original and the proposed structured abstract are apparent. The structured abstract is longer, by approximately 48%. Qualitatively speaking, structured abstracts present greater detail: the purpose is more clearly defined and the methods of identifying, selecting, and extracting information are better delineated.

Evaluation of Structured Abstracts: Their Advantages over the Nonstructured Format

Comans and Overbeke (1990), using criteria from the *Ad Hoc* Working Group, analyzed structured abstracts of original research articles published in three major medical journals: the *British Medical Journal*, the *New England Journal of Medicine*, and the *Annals of Internal Medicine*. They found that the abstracts were clearly written, but lacked information about sample selection, patients' demographics, and statistical analysis.

As a follow-up of the above studies, Tadio *et al.* (1994) set out to assess and compare the quality of a random sample of nonstructured and structured abstracts in the *British Medical Journal,* the *New England Journal of Medicine*, and the *Journal of the American Medical Association* over four selected years. The structured abstracts received significantly higher quality scores than the nonstructured abstracts, which suggests that the structured abstract is preferable to the conventional, nonstructured format in providing complete information. These authors note that the higher quality scores for structured abstracts may be a direct result of the design of structured abstracts. Indeed, the design provides a framework for the information that should be included and prompts the reader in retrieving this information.

Tadio *et al.*'s study found that the following information was reported more frequently with the structured format than with the nonstructured format: study purpose, setting, number of dropouts, interventions, study variables, appropriate numeric and statistical values, and conclusions. The authors note, however, that although the structured abstracts more consistently met the assessment criteria, they did not meet all of them. For both abstract styles,

there is room for improvement in this regard. Imperfect quality scores for structured abstracts may be the result of a lack of space allotted for abstracts in medical journals (usually limited to 250 words) and the inability of researchers to concisely summarize their research.

In the case of review articles, the advantages of a structured abstract over a conventional abstract are the following (cf. Mulrow *et al.*, 1988): First, readers can efficiently identify reviews that are relevant to their own interest and that are scientifically sound; potential sources of bias can be detected; and results and conclusions can be critically appraised by evaluating the methods of identifying, selecting, assessing, and integrating information. Second, authors are given a framework that will help them concisely organize and present the results of their investigations. A greater awareness of the vital elements of a good review article and clearer, more detailed summarizations of review articles may result.

With regard to reading comprehension, it has been shown that structured abstracts significantly improve the reading comprehension of nonnative English-speaking scientists (NNES), but only in a highly specialized context (Salager-Meyer, 1994). In other words, in a familiar context, the structure of the abstract does not have a direct bearing on reading comprehension: a conventionally structured abstract will be as well understood as a structured abstract if the concepts expressed in the abstract are familiar to the reader. Conversely, if the concepts expressed are highly specialized, then NNES will understand better and in less time a structured abstract than a nonstructured abstract.

Conclusions

All in all, then, although there have been objections (based on length and aesthetic concerns) to the structured format, because of its numerous advantages the structured format has been adopted widely in one form or another, and there is general acceptance that it is more informative than the unstructured variety. Structured abstracts improve both the quality of the paper and the reader's understanding; they result in easier recognition of relevant and valid articles, more precise and efficient computerized literature searches, and quicker, more consistent peer-review processes. Structured abstracts, moreover, unmask methodological problems that were left out in traditional abstracts.

Medical English: Conferencing

P Webber, Universita degli Studi di Roma 'La Sapienza,' Rome, Italy

Background

Linguists have devoted more attention to the study of written science than oral communication of research. In the medical field, this is partly because reading abilities and providing access to the literature are seen widely as priorities for medical professionals, not only for research purposes but also for clinical practice.

The topic has not been entirely neglected, however. Dubois (1980a, 1980b, 1982, 1985, 1987) published a series of articles on short biomedical presentations. These treated many aspects of conference language, from the genre and structure of biomedical talks and intonation to the use of imprecise numerical expressions.

Dubois described both linguistic and nonlinguistic aspects of short papers presented at the Federation of American Societies for Experimental Biology. Among these is a study of nontechnical arguments found in the talks. Starting from the observation that the main purpose of this discourse is to persuade a skeptical audience, she noted the "pre-speech arguments," such as the prestige of the speakers and the title and abstract of their paper, and the "speech arguments." such as the display of confidence in the delivery of the talk, presentation of self as a reliable authority on the topic, and the judicious use of a variety of styles ranging from formal to informal. Finally, there are "post-speech arguments" brought to bear during the discussion phase if the speaker is competent at answering the questions.

Apart from paper presentations, Dubois also published an article on the poster session (1985). She mentioned the reasons for the growing popularity of poster sessions and described some principles of layout and presentation of posters, designed to attract attention and present experiments as clearly and concisely as possible. Presenters stand near their poster while the other participants mill around, stopping to ask questions. This kind of session is less threatening and stressful than speaking from the podium, particularly for novices. Dubois described some typical linguistic realizations of the interchange and noted the great potential of the poster session for classroom use (see also Webber, 1986 and Shalom, 1996).

The pioneering work by Dubois did not lead to any further research until some years later, when more studies appeared, written by Shalom (1993, 1995, 1996) and Ventola (1993, 1996). Although these are mostly on conferences in other fields, they are very interesting because the characteristics described in monologues from other disciplines are often relevant to medical discourse. Shalom analyzed research process genres and participant roles in ecology and humanities conferences, describing the main characteristics of the discussion and the new genre of the poster session discussion. She noted that discussants seemed to focus on certain aspects of their research listed as 'Focus Categories.' An interesting problem in the analysis is the distinction between accepted knowledge and assumptions. At these events where data at the frontiers of research are presented, the experts may not always agree about what is "accepted knowledge." The distinction proved to be so fuzzy that they were collapsed into the one category of 'assumptions.'

The role of the Chair (Shalom, 1995) is central to chaired sessions, such as paper presentations. The Chair opens and closes the session and introduces the next speaker, so that turns are partly pre-allocated. If there is a discussion phase, the Chair opens the paper to the floor and allocates discussants, who bid for turns to ask questions. This is very different from the joint construction of conversation. The Chair operates through a series of discourse moves that may be either procedural, serving to manage the discussion and keep speakers to a rigid time schedule, or social, fostering social cohesion in the group.

Thompson (1994b) included some medical data in a study of three important aspects of cohesion in monologue: clause relations, lexico-grammatical cohesion, and intonation. These three aspects are interrelated and are drawn on by the speaker to signal the overall discourse pattern, thus aiding listeners in real-time processing of the text. The role of intonation is particularly important in spoken communication of science as it also conveys part of the meaning of the text. This partly compensates for the lack of graphic features that are present in written texts, such as text layout.

Ventola (1996) analyzed the discussion phase and the linguistic relations between paper presentations and their discussions as speech events, addressing the problem of classifying them as linked or separate speech events.

Ventola *et al.* (2002) edited a book entirely devoted to conference language, in which the chapters by Rowley-Jolivet (2002) and Webber (2002) include descriptions of medical data. The latter provides an analysis of the question and answer session. This

post-presentation discussion phase presents difficulties for both the presenter and the discussant asking the question, because the development of the interaction is unpredictable and underlying conflicts may be brought into the open. Questions expressing criticism were found in this study to be quite frequent (30% of the total), showing that the discussion phase often represents an opportunity to challenge or attack other researchers.

As noted by Rowley-Jolivet (2002), the work presented is often in a preliminary stage and may be considered an example of "science in the making." She traced the construction of scientific knowledge claims from their early stages in the laboratory to their fully fledged stage as generally accepted facts published in refereed journals. In this development, she assigned the status of proto-claim to the knowledge claims put forward in conference presentations. The same author has published a study of visuals in conferences.

Session Types

The genres of conference discourse vary considerably from one discipline to another, but most include paper presentations of research, plenary lectures, and poster sessions. Some conferences also include state-of-the-art lectures, symposium talks, workshops, current issues, round-table talks, meet-the-professor sessions, fireside panels, and luncheon panels. The conditions of production of these different types also vary considerably. Thus, for paper presentations and posters, an abstract must be submitted to the organizing committee before the meeting. It must be written according to the association's regulations and competes with other abstracts for admission. In fact, only a small percentage are accepted. Abstracts are not submitted for plenaries or symposia. Papers and symposia are followed by a discussion phase, whereas plenaries are not. This is summarized for the main session types in Table 1.

Table 1 Characteristics of main session types

Type	*Abstract*	*Discussion*	*Included in abstract book*
Plenary	No	No	Title only
Paper presentation	Yes	Yes	Yes
Poster	Yes	(Personal interaction)	Yes
Symposium	No	Yes	Title only

Papers are in some ways similar to written medical articles, studied by Adams Smith (1984), Salager Meyer (1993), and Nwogu (1997). They usually start from what is known on the topic, to position the study, and then indicate an unknown or gap before moving on to provide an explanation or solution, which is usually evaluated at the end of the text. However, oral presentations often devote less space to positioning and to the conclusions, whereas they focus more on the data presented in the slides. The speaker's claims and commitment are stated explicitly and forcefully, often using the present tense, which gives the impression of a live issue. Table 2 shows an example of the schematic moves in a paper presentation.

The plenary is different. Speakers have been invited, have submitted only the title of the lecture, and are free to follow any format of their choice. Moreover, the plenary does not have to compete for an audience as there are no concurrent sessions. The plenary is therefore likely to be given by an experienced lecturer of prestige. Lecturers will often give a chronological overview of the way the field has evolved over the years, ending with comments on the outlook for the future. They provide the emerging view of current issues. As a result of the less rigid text structure, they tend to use more overt text markers providing a clearly organized framework.

Features of Conference Language

Some speakers prefer to read from a text written out before the conference and many rehearse their talk carefully. In fact, the talks retain features of writtenness generally considered characteristic of the scientific register, such as detachment, precision, and a high occurrence of specialist terminology. However, they differ from the written article owing to the

co-presence of the interactants. This leads to more expressions of uncertainty and hence modality, including modal auxiliaries such as *might* and subjective forms of modality such as *I think* or *we are not sure*. Epistemic devices and hedging (*see* **Medical Discourse: Hedges**) are used partly for reasons of politeness, to give an impression of modesty and caution. However, they also reflect more exactly the speaker's confidence in the propositions and the reliability of the data.

Webber (2004) compared a conference abstract, a paper presentation, and a research article on the same topic. The strategies used in the three text types are affected by the purpose of the text and by the limited space and time available for the two conference genres. The conference abstract is a very condensed version of the work presented. It is submitted before the conference and, to compete with other abstracts, it tends to stress the novelty and interestingness of the study described. It focuses on the purpose and main claims of the research and hence starts immediately with a statement of the purpose. The oral presentation includes features of politeness and opening and closing frames, a part of the interactional ritual of the conference. The opening and closing frames serve to greet the audience or express thanks, such as *it is pleasure to be in this beautiful city* and *Thank you, Mr. Chairman*. In the research article, themes are longer, more complex, and less suitable for oral communication. The results and conclusion sections are longer and devote more space to comparing the results with those of other researchers and accounting for discrepancies.

Time constraints are important factors, especially in paper presentations, which are generally allotted only 10 to 15 minutes for the presentation and 5 minutes for discussion. Mastering conference skills thus presents difficulties for speakers and listeners, since much cognitively demanding information is presented in a short time and, apart from the discussion phase, listeners have no opportunity to check or ask for confirmation. This is particularly difficult for non-native speakers of English when faced with the task of understanding a range of different accents as presenters follow one after another in rapid succession, especially if the listeners have learned English in an idealized, perhaps written form.

Conclusion

Certain features are typical of oral communication of medical research. There are frequent instances of language in action, as speakers refer to the slides. As already noted by Dubois, slides are "the backbone of the speech." They are an important distinguishing element in conferences, as they not only provide the evidence on which the researchers base their argument but also aid the listener in following the content, together with intonation, lexical cohesion, and explicit signaling of the discourse organization of the text using markers such as *This talk will focus on* ... and *now let me turn just briefly to* ... Each slide generally introduces a new unit of discourse. The co-presence of participants leads speakers to use features such as narrative elements, informal language, hesitancy markers, occasional anecdotes, jokes, and references to difficulties encountered in doing the research. These are partly a result of on-the-spot decisions, may be motivated by both conscious and unconscious choices, and realize the role of equals. Most of these would not be countenanced in written articles and are edited out of the final version if it eventually is published. Features of informality are also found. Among the informal features found by Dubois in her material are imprecise numerical expressions, such as instances of hedging (*a little*, *a bit*, *around*) and ranges (*anywhere from 150 to 200*), used not only because aural processing of conference talks is difficult but also because speakers wish to highlight certain data and downplay others that they consider less important (*see also* **Medical Discourse: Hedges**).

Much of the preliminary research presented may not be published. This unpublished work is thus nipped in the bud and never reaches a wider audience. The conference may be the only opportunity to hear about this new research. Thus, novelty is one of the main characteristics of the conference. The choice of language in the titles and conference abstract is designed to try to make the contents appear newsworthy. Particularly in the many concurrent sessions there is competition to attract an audience. In addition to the competition, however, there is also a desire to create a sense of solidarity and in-group affiliation with the audience, where the speakers tend to present themselves as persons and not just researchers. Hence, we find instances of first-name familiarity and a frequent use of personalization, such as the use of the first-person singular and lexical phrases such as *in my opinion*, which lower interpersonal distance and create a sense of rapport in a situation that represents a challenge and involves risk. Webber (1997a) found many instances of conversational features, particularly in the discussion section. The discussion, however, is not a true conversation because serious business is being accomplished and it includes transactional as well as interactional work. The strategies used in different types of medical English vary in ways often characteristic of the genre that they represent. The linguistic behavior observed is partly

rule governed in the sense that members of the discourse community will expect a conventional form of discourse from participants.

The discourse is also affected in part by the participants' motives for attending these conferences. Participants wish to keep abreast of important developments in their field, but the conference is also a social occasion where people can meet the speakers and contact other researchers to exchange news and views. The coffee breaks and conference dinners are thus also important parts of the conference. All these aspects make the study of conference language complex but fascinating.

Medical Journals, Letters to the Editor

D Carnet and A Magnet, University of Burgundy, Dijon, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Among the seven genres identified in medical journals (Webber, 1994), along with research papers, review articles, editorials, book reviews, case studies, and the news section, letters to the editor are a tool offered to the community to react to other scientists' research and mainly to express personal opinions and disagreement. The experimental article, in contrast, is known as a constrained and modelized mode of written communication and was set up as a genre following J. Swales's (1990) archetypal studies. Thus, letters to the editor offer a much freer mode of expression than the classical scientific rhetoric, which is described as objective, purely referential, impersonal, and detached. They do not only offer researchers an open forum in which to give full vent to sometimes harsh criticism, but they also contribute to the validation process of new research by 'invisible colleges' (Crane, 1972). Although research papers are evaluated before being published, much of the process of evaluation comes after publication. Thus, evaluation goes on formally through their citation in other papers that undergo the same process of review and informally in letters to the editor published in medical journals (Bloch, 2003) (*see* **Medical Discourse and Academic Genres; Collocations; Discourse Domain**).

Historical Background of the Genre

Origin of These Letters

Letters can be traced back to the very beginnings of scientific writing. The first scientific publications were letters enabling scholars interested in scientific observation and experiments to exchange information. At the end of the 17th century, researchers published exclusively through correspondence printed in journals. Indeed, letters have been described as "a longstanding tradition in scientific journals written in a predominantly personal style, with use of the first person" (Webber, 1994: 258); and in most medical journals, letter publishing began in the 19th century, generally at the same time as the birth of these journals. For instance, the first letters appeared in issue 2 of *The Lancet*, on October 12, 1823, in a section entitled 'Miscellaneous.' They first appeared in 1848 in the *Transactions of the American Medical Association,* which became *The Journal of the American Association* (*JAMA*), in 1883; in the *British Medical Journal* (*BMJ*) in 1857; and in the *New England Journal of Medicine* (*NEJM*) in 1928. Letters to the editor can be considered a long-standing yet lively genre updated through time.

A Habit Inherited from the Quality Newspapers

This type of correspondence shares common features with letters published in the quality papers of the European press and can be defined as a paper or article presented as a letter, dealing with a contentious issue in a controversial tone written by a member of the public. A diachronic overview shows that over time the letters have increased in length, number, and regularity. However, the number of letters published in each issue may still vary on average from 5 to 20 letters, depending on the journal.

A Complement to Research Articles

Their *raison d'être* also evolved over the years, progressively becoming a genuine and mature genre. From mere clarifications aiming to provide further knowledge on a given research topic, they gradually became a tool for questioning previously validated research. They have grown as a complementary, and sometimes alternative or transient, strategy used to build a niche, establish a position, and defend it in the scientific community.

Characterization of the Genre

These letters are present in most medical journals. However, they do not always bear the same name. Investigating the top medical journals following the impact factor as established by the *Science Citation Index* (*SCI*) shows that the most common title used to label this genre is 'Correspondence.' It is called this, for example, in *Nature Medicine, The Lancet, The New England Journal of Medicine, The Journal of the National Cancer Institute,* and *Gastroenterology.* However, other titles can also be observed, such as 'Letters,' in *The Journal of the American Medical Association* and 'Reader's comments' in *The American Journal of Cardiology.*

Letters to the editor do not belong to the epistolary genre. They are not really letters but a way to express one's opinion or to set something straight. They often start with the characteristic head shared with the epistolary genre, 'Sir' or 'Dear Sir.' Interestingly enough, it can be observed that 'Dear Sir' typifies American journals, whereas 'Sir' is the standard form in British ones. Quite a lot of other journals publish this correspondence with the heading 'To

the Editor,' and, as in any scientific writing, communication actually builds up between a scientist and his or her community and not between two individuals.

This communication mode should, in fact, be considered as deriving from 'the open letter' genre, thus borrowing some of the polemic journalistic features, and not be viewed as life writing, characteristic of the epistolary genre.

Writing Conventions

Medical editorial boards very often provide specific guidelines for potential authors. These indicate the maximum length (between 300 and 1000 words), the deadline to react to a published article (between 1 and 6 months), and the nature of the issues that can be tackled. They can either be comment letters on what has been previously published in the journal or letters of general interest unrelated to earlier items in the journal. Letters can be modified by the editor without any prior agreement from the authors, and letter writers are generally not consulted before publication. The letter must not have been published (including on the Internet) nor be under consideration for publication elsewhere, and letters that contain unpublished data are refused by some journals. Correspondence letters are not usually peer reviewed, but the journal may invite replies from the authors of the original publication. In a few journals, it is even specified that only one table or figure is permitted and that no more than five references and five authors should be included. Authors are also required to suggest a title.

Objectives and Strategies

In the scientific community at large, scientific claim is essentially expressed by the research paper through the use of validated protocols, by the publishing of experimental findings in journals ranked according to their impact factor, and eventually through the reviewing process. Letters to the editor represent a form of contradiction *per se* of the research paper. They appear to be on the fringes of the community-validated discourse, but they may be interpreted as a dynamic process leading to discourse production as well.

Controversy generally concerns the experimental method selected, the duration of the experiment (most of the time too short for financial reasons), the number of experimental subjects (most of the time too few for the same reasons), and results too flimsy or too frail to be exploited. Indeed, they do not only occur as a reaction to the published discourse. They can also precede the publication of scientific papers because they very often relaunch new research on a given theme. This type of discourse can therefore be seen as constructive contradiction.

Authors' Objectives

The objective for an author is not merely to write a letter and let other scientists know his or her opinion about a specific topic. If this were the case, such letters would have disappeared long ago and would perhaps have been replaced by e-mails, which are currently a much more direct and rapid way to communicate. Conversely, correspondence in scientific journals does not aim to resolve private issues. The letter writers require the entire community to witness and even take part in their public debate.

The strategy of questioning can be understood as an explicit and implicit mode of criticism leveled at an established scientific fact. It is the quickest way for them to position themselves on a research theme considered to be 'hot science' on which they are also working because having a paper published takes several months at least. To submit an article, scientists must have gathered enough evidence through their results, whereas a letter will allow them to stake out their territory before all the conclusive evidence is available for publishing. It may also be the means for a researchers to highlight or rehighlight their own published research, which otherwise might be discredited or ignored due to the publication of an article that contradicts their own results.

Writing letters to the editor may appear to be an irrepressible need for some scientists because it allows them to react swiftly, personally, and sometimes contentiously to issues about which they feel strongly concerned.

A Community's Strategy

It is noteworthy that editors still grant space to correspondence in their journals even though the publishers of medical journals generally complain about the increasing size, and hence the publishing cost, of scientific journals. The editor acts as a vector, and the letters are used as tools in the general process of scientific validation; they can be considered as the aftermath of the construction of the scientific fact. Indeed, in contrast to scientific conference forums or discussion forums on the net, their journals offer permanent records of a debate. They are public, can always be consulted (either in the paper version or the online version of the journals), and can even be quoted as references in bibliographies.

Readers' Motivations

Most researchers read letters not systematically but regularly in one or several journals. It is a matter of

keeping informed about the hot issues in their fields and to learn about the contentious debates within their specialists' community. Researchers do not systematically read the correspondence section after the publication of an article they have written. This shows that they are not particularly interested in the reactions their papers may trigger or that the validation granted by the reviewers brings them enough satisfaction and confidence in their research. Skimming letters seems to be a quick and efficient means for researchers to keep up to date with the new paradigms, to hear about current controversies in their communities, and to learn about various conflicting reactions to previously published articles.

Discursive Features

Such letters reveal underlying conflicts in the community that are totally ignored or hidden in the experimental research paper. Several linguists (Hyland, 2000; Magnet and Carnet, 2001; Bloch, 2003) suggest that this major difference necessarily induces specific features in the writing.

A Chronological Approach

In the research paper, chronology is totally erased. In contrast, in letters to the editor, the authors are relatively time-conscious. Generally, the letter follows a chronological approach linked to the contentious character of the genre. It mimics more closely, in a way, the prosecution and plea process observed in courts; here, the board of editors and the scientific community at large act as jurors. Letters can thus play a role in the questioning process of the scientific community. They offer the scientist a way to react publicly, almost in real time. They can, in some cases, be a step toward publishing results in the form of an experimental paper.

A Modelized Macrostructure

A basic feature of letters to the editor is their underlying macrostructure, whose most common pattern can be described in four moves. Adapting J. Swales's famous descriptive analysis mode of the conceptual organization of the research paper (Swales, 1981), the following recurrent model can be suggested. The first move is a reminder of the contested published results. The other three reproduce the logical argumentative pattern: thesis – antithesis – synthesis. Thus, the second move aims at expressing the challenge. The third develops arguments backed by the author's own research. Finally, in the fourth move, the author urges his or her colleagues to reconsider the initial findings of the study under attack before reaching their own conclusion.

An Author-Reader Relationship

The research paper focuses on the object of the research and, hence, any form of subjectivity tends to be erased. It almost looks as if there were no subjects in charge of the experiment. On the contrary, letters to the editor are presented as a pseudodialog in which addressers speak in their own names. Addressees are supposedly the editors of the journals, but, in reality, letters are sent to the community of specialists at large. This personalized form of communication is therefore characterized by the recurrent use of the first-person pronouns *we* and, to a lesser extent, *I*; by the intensive use of the possessive *our*; and by the frequent opposition between *we* and *you*, *we* and *they,* or *we* and *he*. These are clear signs of the opposition between the scientific fact as reported in the primary article and that proposed by the authors of the letter. With this opposition, the strategy aims to weaken the credibility of the scientific fact as established by the experimental paper. This process allows the authors of these letters to prove that there is not only one established fact but at least two.

A Researcher-Centered Genre

Contrary to the primary scientific article, which aims to establish scientific facts, letters to the editor tend to be focused on the researchers themselves and their position in the community. They take into account the authors' reputation in the community, for example, and disagreement on scientific issues may disguise clashes of interests. From research papers it may look as if the sole aim of researchers is scientific progress, whereas from letters to the editor conflicts and competition become explicit. The experimental paper can therefore be described as research-centered, whereas letters to the editor tend to be researcher-centered. This is why self-mentioning and self-quoting are common practices in this genre. Moreover, it is worth noting that most of the time letters are signed by only one scientist, unlike research articles, which most of the time are the fruit of collaboration in the medical field. This change in focus influences linguistic choices and induces cultural specificities.

Linguistic Features

Specific Verbal Forms

An interesting point is the very low occurrence of passive structures in letters to the editor. Scientific discourse is generally characterized by a heavy use of the passive, especially in the 'Materials and Methods' and the 'Results' sections of papers. The reason for this is to focus on the object of the experiment, rather than on the subject, to give an objective value to the

published research. In letters to the editor, on the contrary, the emphasis is put on the choices made by the criticized authors and thereby on the authors of the letters themselves. Thus, selecting active forms to build an argument strongly reinforces the contentious mode.

The most common grammatical tense used is the simple present (approximately 50% of the cases), and this again contrasts sharply with the research article, in which 80% of the verbs are in the simple past. In letters to the editor, the simple past is used in only 35–45% of the cases to report the experiments carried out by the criticized authors or by the authors themselves. The simple present is chosen to express the reality of the article in question. It is neither the historical present nor narrative present; it refers to the established scientific fact. This peculiar use of the present tense is close to a journalistic style. It has no connection with chronological time and follows Quirk's (1997) interpretation: "The implication of the present tense seems to be that although the communication event took place in the past, its results – the information communicated – is still operative. Thus the notion that the past can remain alive in the present also explains the optional use of the present tense in sentences referring to writers and composers and their extant works."

Modality

Modals represent only 10% of the verbal structures, lower than the percentage in research articles' 'Discussion' sections, in which they represent 14% of all verbal forms (Magnet, 1992) and in which they most often have an epistemic value.

Epistemic Modality or Hedging Scientific discourse is generally used to weigh evidence and draw conclusions from data. Thus, uncertainty and doubt are necessarily present at least in the 'Discussion' section of experimental papers. This is expressed through hedges, which account for various degrees of probability (Salager-Meyer, 1994, 1995). Scientific discourse deals with the problem of what is true or false; the particular value of this modality is that it expresses the utterer's lack of certainty regarding the validation of the predicative relation.

In letters to the editor, in contrast, epistemic modality (hedging) has a low occurrence. The most frequently used modals are *should, could, may,* and *would* and to a lesser extent *can, must, will,* and *might*.

Root Modality In contrast to epistemic modals, root modals may convey a deontic meaning to indicate a form of moral advice, expressing, in fact, strong pressure from the utterer on the criticized authors. Linguistically, it thus concerns the relationship between the grammatical subject of the utterance and the predicate. Root modals are not concerned with the truthfulness of the subject-predicate relation but, rather, serve to express orders, wishes, suggestions, causality, or capacity. Indeed, the most widely accepted view is that hedging is the process whereby authors tone down their statement in order to reduce the risk of opposition, so it is understandable that, in letters to the editor, authors should express themselves instead through root modality. This type of moral advice through which the utterer exerts pressure on the criticized authors applies to objects and hence makes distancing possible. However, root modality can also bear on the animate subject, here, the criticized scientist.

(1a) "First the degree of oxidant stress **should be assessed** to choose an effective antioxidant regimen." (*The Lancet*, 2001: 631)

(1b) "Respectfully, I **must suggest** we **should** all **beware** of inaccurate invectives." (*The Lancet*, 2001: 647)

Modality of Assertion Positive assertion needs no particular marker, whereas any manipulation of the assertion calls for a specific marker. One of the most recurrent forms of manipulation in letters to the editor is contradiction, linguistically expressed through negation. The aim of the authors is to deny the original utterance or rebut its scientific relevance. Negation may be total or partial. It may apply to verbs or nouns, to the criticized research, or even to the researchers themselves.

(2) "It **makes no sense** to me that it is possible to reliably detect the so-called independent associations of individual constituents of this group, when . . ." (*AJCN*, 2000: 849)

Qualifying Modality Qualifying modality concerns judgments about the content of the predicative relation, for example, whether it is good, bad, normal, abnormal, fortunate, or unfortunate. This is essentially qualitative modality, and in letters to the editor it mostly conveys a derogatory judgment.

(3) "The method they use **does not seem to be suited** to the end results." (*The Lancet*, 2001: 553)

Adjectives and Adverbs In contrast to the depersonalized style observed in the experimental paper, giving vent to direct criticism in letters to the editor is accepted by the community. These critiques borrow from the derogatory style, illustrated by the use of

specific figures of speech. One of the common ways to belittle one's opponents is to use highly disparaging terms to qualify their work, such as *poorly, mistakenly, biased, emotive, confusing, too simplistic, old and outmoded, artificial, vague, speculative,* and *sad*.

Nouns and Verbs Letters also reveal a massive use of certain nouns and verbs that are totally absent from the research paper because these derogatory terms usually belong to the critical style and reflect strong subjectivity. Nouns such as *critique, rebuttal, borderline, reductionism,* and *blurring* and verbs such as *refute, rebut, fail to, contend, disagree, reject, challenge,* and *invalidate* are common in letters.

Negative Prefixes in Adjectives In standard English, the adjective is a linguistic tool mainly used to specify and qualify the notion expressed by the noun. In scientific discourse at large, adjectives mostly express a quantitative value, whereas in letters to the editor, an extensive use of qualitative adjectives can be observed. Interestingly enough, most of them carry a negative prefix whose aim is to weaken the arguments set out in the targeted paper. Examples of these prefixes are *in-* (*inappropriate, inaccurate, inconsistent, incomplete, intemperate, incorrect, implausible,* etc.), *un-* (*unreliable, unexpected, unproven, unsupported, unclear, unaware, unfounded, unfortunate,* etc.), *out-* (*outmoded,* etc.), *under-* (*underpowered, understated,* etc.), and *mis-* (*misleading, misused, misdirected,* etc.).

Specific Markers Specific markers are necessary to build an argument. In letters to the editor, these markers fall into four groups that all express disagreement but with different levels of intensity. These markers correspond to four discursive strategies.

- Concession. The weakest markers used to contradict somebody's opinion express concession. They are common to all forms of discourse, including the research article. The most recurrent forms present in letters to the editor are, for example, *although, however, but, yet, nevertheless, nonetheless, even if,* and *even though*. These markers are used to diminish or belittle the impact of published observations and conclusions.
- Antithesis. Authors may wish to express their opposition in a stronger way. In order to do so, they select markers such as *but, while, whereas, conversely, by contrast, in contrast, otherwise, instead, unlike,* and *opposite*. This linguistic device aims to oppose two ideas, two protocols, or two methodologies to demonstrate the superiority of the supported team.
- Rewording. Some markers are used to reformulate a previous statement and incite the criticized authors to change their minds and possibly their methods or conclusions. It is, in fact, an illustration of the pragmatics of politeness (Myers, 1989) generally observed in scientific discourse. Examples of these markers are *rather, better, more accurately,* and *in other words*.
- Doubt. The most subtle way of explicitly questioning a method is to raise doubts concerning the validity of the study. The most common words and expressions used in letters to the editor to mark this are *maybe, perhaps, probably, highly unlikely, wonder whether,* and *far from verified*.

Understatements

The use of implicit disagreement can be considered to be a less direct way to modulate contradiction. This weak contentious mode tends to express the utterer's disagreement with the work under debate through forms that invariably involve a reference back to the utterer. Examples of these forms are *we find it surprising that, therefore we strongly suggest, therefore we think, I have several comments, I showed clearly, In my opinion, we believe, we are aware,* and *we advocate doing this*.

By asserting their own results, letter writers actually contradict and criticize the results of the studies they are referring to. It can be understood as implicit criticism. This implicit mode of criticism is more frequently observed in American journals than in British ones, and it may be interpreted as a good example of the American tendency toward political correctness.

Medical Terminology

Letters to the editor, along with the other six genres in medical writing, display specific linguistic characteristics, the most salient and obvious feature of which is the strong presence of a medical nomenclature used for labeling and description. The great majority of medical terms are nouns derived from Greek or Latin roots. This recurrent presence of a highly specialized vocabulary makes the letters to the editor as difficult for the layman to understand as the research papers, which confirms that this mode of communication truly belongs to the world of scientific discourse.

(4) "The suggestion by Ozols that the dose of **carboplatin** could explain our results is implausible, because the same **carboplatin regimens** were used in the **control arm** and the **test arm**." (*The Lancet*, 2002: 2088)

Cultural Features

In spite of the common features shared with general scientific discourse, letters to the editor in Anglo-American medical journals allow their authors some freedom of speech and style, which is never found in research papers. Whereas research articles are always built in the same way, with the same apparent objectivity and neutrality, the style of the letters may vary from one journal to another, from one author to another, and even from one country to another.

Differences between American and British Letters

The tone and style used in American and British journals are often in stark contrast. In American journals, considerations of political correctness lead to the focusing of criticism on the object (the experiment or the selected methodology) and not on the subject (the research team). This attitude induces the letters' authors to use understatement and hedging through modalized forms.

In contrast, British journals abound with overtly polemical phrases, which may even be aggressive or sexist (e.g., *inappropriate, inaccurate, emotive, poorly designed, retrospective,* and *biased*). This type of overt criticism illustrates both the researcher-centered attitude previously mentioned and the lack of restraint observed in some British letters.

(5a) "I think that Sandra Simkin's report is **inappropriate**, **inaccurate**, and **emotive**." (*The Lancet*, 2001: 641)

(5b) "We are **astounded** that such **frivolous** allegations should have been made by academics from a reputable school of public health." (*The Lancet*, 2002: 1982)

Titles Borrowing Cultural References

Some letters bear a title that could never be found in a research article. These titles may conjure up a cultural background supposedly shared by the whole scientific community but that actually is familiar only to native speakers. References can be cultural and/or humorous.

Bible Quotations In some cases, English-speaking writers disguise their biting critique as cultural references by including quotations from the Bible. Even though the Bible is a universal cultural heritage, it is well known that it is more prevalent in Anglo-Saxon culture. It would therefore be difficult for a non-native speaker to understand the hint and even more so to borrow from the cultural background to express a criticism in such a way. It is through irony that a phrase borrowed from the New Testament "Ask and it shall be given you; seek and ye shall find" (Matthew VII:7; Luke XI:9) is to be interpreted as particularly disparaging toward the methodology of the scrutinized team.

(6) "**Seek and thou shalt find**
Patino *et al.* doubt the presence of endotoxin in their study cohort, although we know it to be present in the general population. Higher endotoxin levels in patients with diabetes mellitus and arterial disease may be expected and should be sought." (*AJCN*, 2000: 1054)

Literary Quotations English-speaking scientists also share a common literary heritage that they enjoy borrowing from, thus mimicking newspaper headlines. Shakespeare is, of course, a favorite, and, because some quotations now belong to universal culture, it can be assumed that they will be understood by the whole community of researchers, native and non-native speakers alike.

(7) "Acute hepatitis virus infection: **to treat or not to treat**." (*Gastroenterology,* 2004: 1219)

Neologizing The use of impish neologisms to reveal the inadequacy of a terminology commonly used in the scientific community is truly meant to ridicule their authors. For example, the use of the word *vegetarian*, considered too vague and inaccurate, is criticized. This leads the authors in (8) to all sorts of ludicrous and wild variations on the theme.This is indeed a humorous criticism of scientific popularization of terminology used by a community that usually claims a highly specialized vocabulary.

(8) "In an attempt to add more specificity in the scientific literature, various qualifying terms for **vegetarian** have been used, such as **pescovegetarian** and **lactoovovegetarian**. For one person I know who considers himself a vegetarian, an appropriate label might be **lactoovopescopoulo-steak-only-when-I-eat-out vegetarian**." (*AJCN*, 2000: 1211)

Sayings Authors sometimes borrow sayings that can be, for instance, aphorisms, as in (9a). The authors of the letter criticize their colleagues' lack of professionalism because they were unable to detect subtle changes that are likely to have dramatic health consequences. Others borrow from popular songs, as in (9b).

(9a) " '**Small is beautiful**': α-linolenic acid and eicosapentaenoic acid in man [. . .] Minor changes in dietary lipids may be most significant in thrombosis prevention." (*AJCN*, 1999: 1169)

(9b) "Mechanical circulatory support—a **long and winding road.**" (*AJCN*, 2000: 1222)

Reference to a common non-scientific cultural background characterizes the genre letters to the editor, as opposed to the research article, and may explain why letters built on such cultural references are seldom written by non-native writers. All these techniques are based on irony and humor through the use of phrases borrowed from other genres, generally out of reach for non-native speakers.

Status of the Genre: Diffusion and Scope of Letters

One of the reasons researchers still spend time writing letters to the editor is that their diffusion is much easier and faster than that of research papers. For example, 33% of the letters received by *The Lancet* are actually published, whereas only 10% of submitted articles end up being published (Mullan, 2003). The refusal of a letter is often justified by the editors as being due to their readers' lack of interest, but in fact less politically or scientifically correct reasons may also explain rejection (Behe, 2002).

For the community, a mere letter on a hot research theme in a highly ranked journal may be the first step toward questioning a well-established paradigm. Indeed, a letter may be the favored means to start open exchange with a competing team. This sort of publishing may influence the standing of some researchers in the community. However, this influence will only be effective if the authors already have a good reputation among the specialists and if their laboratory results are brought as evidence to support their point in the debate. This relational mode is deemed satisfactory and rather efficient because it enables scientists to inform, in a quick and efficient manner, more people than a mere presentation in a conference. This may allow researchers to establish a niche before submitting more substantial results for publication. Finally, it also allows some researchers to defend an experimental protocol that has been much criticized by peers.

Trends and Prospects for Letters to the Editor

Letters can be seen as a useful, and even necessary, but not self-sufficient communication tool within the scientific community. They reflect tensions in this community. Their most interesting role is to provide researchers with an outlet for frustrations, oppositions, controversies, and disagreements. Letters enable them to escape from the formal and impersonal constraints of the research article style. Above all, they may constitute a breeding ground for new research by bringing up new ideas, new paths to explore, or new prospects for future collaborations. That is why these letters still play a key role among the scientific community at large, and this also explains why numerous online scientific journals have kept a section devoted to correspondence, thus a genuine and enduring genre. However, letters to the editor usually do not represent some sort of true validation because, unlike the research paper, there is no reviewing process.

This genre does not offer an equal opportunity to the international community of researchers. It is a mode that non-native speakers find hard to master. Irony, humor, and cultural references that are difficult to tackle in a foreign language may explain why native English speakers represent the vast majority of the authors of letters to the editor in English-language journals.

Primary Care Medical Encounters

The majority of research in linguistics on the discourse of medicine has focused on primary care encounters, that is, routine encounters in pediatrics, family medicine, gynecology, and internal medicine that take place in offices or clinics. This research has contributed a great deal to our understanding of how the phases of a routine medical encounter are structured, how its interactional sequences are organized, and how its discourse creates and reflects a variety of dynamic contextual dimensions.

The Structure of Medical Encounters

Following Byrne and Long (1976), ten Have (1989) described the phases in the structure of a routine medical encounter as follows:

- Opening
- Complaint (discovering the reason for the visit)
- Examination (medical history and physical exam)
- Diagnosis
- Treatment or Advice
- Closing.

Each of these phases is associated with particular interactional sequences: social talk in openings and closings, although this small talk is not inconsequential; question–answer for discovering the reason for the visit and conducting the history and physical; medical assessments and explanations for diagnosis; and imperatives and instructions for treatment.

This linguistic description of the structure of a medical encounter corresponds roughly to the structure of the medical interview as described in the research and teaching literature in the field of medicine. (There is an enormous amount of research and teaching literature on the topic of medical communication in medicine itself, which I draw on but do not review systematically here. I rely heavily on Aldridge (1999) and Roter and Hall (1992) for this purpose.) Aldrich (1999), for instance, lists the following:

- Introduction
- Chief Complaint
- History
- Review of Systems and Symptoms
- Physical Examination
- Diagnosis
- Treatment Plan
- Closing.

Within the history, Aldridge identifies several areas, including history of the present illness, past medical history, family history, and socialpsychological history. Aldridge also notes that the review of systems and inventory of symptoms is typically organized by working head down as the physical examination takes place (HEENT (head, eyes, ears, neck, throat), chest, heart, abdomen, genitalia, skin and extremities, neurological), although the currently recommended practice is to organize this review by organ

Primary Care Medical Encounters

The majority of research in linguistics on the discourse of medicine has focused on primary care encounters, that is, routine encounters in pediatrics, family medicine, gynecology, and internal medicine that take place in offices or clinics. This research has contributed a great deal to our understanding of how the phases of a routine medical encounter are structured, how its interactional sequences are organized, and how its discourse creates and reflects a variety of dynamic contextual dimensions.

The Structure of Medical Encounters

Following Byrne and Long (1976), ten Have (1989) described the phases in the structure of a routine medical encounter as follows:

- Opening
- Complaint (discovering the reason for the visit)
- Examination (medical history and physical exam)
- Diagnosis
- Treatment or Advice
- Closing.

Each of these phases is associated with particular interactional sequences: social talk in openings and closings, although this small talk is not inconsequential; question–answer for discovering the reason for the visit and conducting the history and physical; medical assessments and explanations for diagnosis; and imperatives and instructions for treatment.

This linguistic description of the structure of a medical encounter corresponds roughly to the structure of the medical interview as described in the research and teaching literature in the field of medicine. (There is an enormous amount of research and teaching literature on the topic of medical communication in medicine itself, which I draw on but do not review systematically here. I rely heavily on Aldridge (1999) and Roter and Hall (1992) for this purpose.) Aldrich (1999), for instance, lists the following:

- Introduction
- Chief Complaint
- History
- Review of Systems and Symptoms
- Physical Examination
- Diagnosis
- Treatment Plan
- Closing.

Within the history, Aldridge identifies several areas, including history of the present illness, past medical history, family history, and socialpsychological history. Aldridge also notes that the review of systems and inventory of symptoms is typically organized by working head down as the physical examination takes place (HEENT (head, eyes, ears, neck, throat), chest, heart, abdomen, genitalia, skin and extremities, neurological), although the currently recommended practice is to organize this review by organ

systems as a separate step in the history (skin, blood and lymph, respiratory, cardiac, vascular, gastrointestinal, urinary, reproductive, musculoskeletal, neurological, endocrine). As in most sources in the medical literature, Aldridge also recommends paying special attention to the psychosocial aspects of the interview, what he euphemistically calls "embarrassing topics," including substance abuse, alcohol use, and financial affairs.

The Organization of Interactional Sequences in the Medical Encounter

In linguistics, researchers have considered the organization of interactional sequences within different phases of the routine medical encounter in detail. In one of the most cited articles in medical communication, Beckman and Frankel (1984) found that physicians interrupt the patient's account of the reason for the visit after only 18 seconds, on average, usually truncating the patient's account of the first reason for coming to the doctor, even though the first reason mentioned is often not the patient's most important reason (Rost and Frankel, 1993). This quick interruption within the complaint phase is often critiqued as one of the problematic means by which physicians establish interactional dominance in the medical encounter, sometimes to the point of actively marginalizing the patient's topics, questions, and concerns (Roter and Hall, 1992). However, in a recent analysis of the complaint phase, Halkowski (in press) argued that the chief function of this phase in the encounter is establishing the "doctorability" of the reason for the visit: in other words, patients must legitimate their need for medical attention, what the sociologist Talcott Parsons called access to the sick role. Heritage (in press) further notes that physicians are oriented to establishing the reason for the visit with their first question and look for patients to indicate interactionally that their account is complete before they move on to the next phase of the encounter, which can happen very quickly, especially in a routine encounter. Heritage argues that the length of this phase is less important than the interactional coconstruction of the chief complaint to the satisfaction of both the physician and the patient.

In the medical literature, a distinction is made between open-ended and closed-ended questions in what is called the medical interview. Physicians most often use an open-ended question to elicit the chief complaint, a question form that allows the patient to formulate an explanatory or narrative response, as in the following examples. [For the convenience of readers from a variety of backgrounds, I present transcribed data in very broad form, regularizing spelling and punctuation for intonation, and not including all features transcribed by the original authors. Three transcription conventions that I should note here are the following: (1) contextual material in double parentheses, e.g., ((physician entering room)), (2) ellipses (. . .) to indicate deleted material from the original source, and (3) double dashes (–) to indicate a break in an utterance, e.g., (you know–).]

DOC: How have you been?
DOC: What brings you in today?
DOC: Tell me about your leg pain. What seems to be the problem?

Roter and Hall (1992) note that physicians use open-ended questions to orient themselves to the purpose of the visit and to gather information in order to begin hypothesis formation toward the differential diagnosis. Physicians then typically move to closed-ended questions for history taking, review of systems, and hypothesis testing of the differential diagnosis, as in the following examples:

DOC: Any heart problems?
DOC: Any shortness of breath?
DOC: Are your leg symptoms worse after standing for a few minutes?

Closed-ended questions are much more frequent than open-ended questions in the routine medical encounter, by a factor of 2 to 3 or more (Roter and Hall, 1992). Although the pedagogical literature on what is called "patient-centered communication" recommends more frequent use of open-ended questions, especially in the complaint phase but also in the history and physical, many physicians continue to regard closed-ended questions as the most efficient means to conduct the medical interview (Roter and Hall, 1992; Frankel and Beckman, 1993; Aldridge, 1999).

Linguists have looked at question–answer sequences in the routine medical encounter in great detail. As Ainsworth-Vaughn (2001) pointed out, questions are a powerful means of establishing and maintaining interactional dominance in an encounter: questions can establish and maintain the frame of the encounter as an asymmetrical interview in which the role of the patient is simply to answer questions posed by the physician, and the form of questions can further restrict patients' contributions, as in a series of closed-ended questions that ask for yes–no or brief answers. In West's (1984) study of 21 family care encounters, she found that 91% of the questions were asked by physicians and only 9% were asked by patients. Noting further that physicians' questions are almost always answered, whereas patients' questions are sometimes ignored in medical encounters

(98% of physicians' questions were answered, whereas only 87% of patients' questions were answered in her study), West (1984) concluded that the asymmetrical form of the medical interview is achieved in large part through the organization of question–answer sequences. Similarly, looking for question-answer sequences where patients initiate new topics, Frankel (1990) found that only 1% of such questions were posed by patients in a set of primary care encounters and argued that medical encounters show a distinct dispreference for patient-initiated questions. Other researchers have found similar patterns of physician dominance through questions and the ways that this interactional dominance establishes overarching schemas and frames as well as control of topics in the primary care encounter (Fisher and Todd, 1993). This interactional dominance in the discourse of medical encounters has been critiqued as promoting the interests and agenda of the physician within a biomedical model focused solely on disease rather than eliciting the understandings and concerns of the patient within a broader biopsychosocial model of disease as well as the experience of illness, in what the sociologist Elliot Mishler famously termed the conflict between the voice of medicine versus the voice of the lifeworld (Roter and Hall, 1992).

Recently, however, researchers have looked more closely at interactional coconstruction in question–answer and sequences in the medical encounter, describing the ways that physicians and patients coconstruct the discourse of medicine within an encounter, a coconstruction of the context that is typical of institutional encounters in general (ten Have, 1991; Maynard, 1991; Heritage, 1997). With respect to question-answer sequences in medical encounters, patients, it seems, use a variety of interactional means not only to answer the question, but also, as Stivers and Heritage (2001) put it, "answer more than the question" and thereby raise their own topics and concerns. For example, in the following exchange, the physician is in the middle of a history sequence with closed-ended questions designed to elicit yes–no answers, but the patient's answer to one question is an elaborated one:

DOC: You have your gall bladder?
. . .
PAT: Well I had a tubular pregnancy once, an' I was too afraid to even ask 'em anything about it. An' so I don't know what they did.

Stivers and Heritage argued that this expanded answer not only provides information but also signals that the patient is afraid of surgical procedures and afraid to talk about them. Boyd and Heritage (in press) noted that patients resist the implications of physicians' questions about lifestyle by answering closed-ended questions in elaborated form. In the following exchange, for example, the patient breaks away from a series of yes–no answers to provide her own characterization of her alcohol use:

DOC: D'you smoke?
PAT: Hm mm.
DOC: Alcohol use?
PAT: Hm: : moderate I'd say.

These studies show that although physicians design questions to serve their purposes in the encounter, patients design answers to serve their purposes as well.

Another phase of the primary care encounter that has received considerable attention in the linguistic literature is the delivery of diagnostic news. Heath (1992) found that although physicians design their delivery of diagnostic news with pauses and other features in order to invite patient response, patients typically respond with silence or only a minimal acknowledgment token, as in the following sequence (pauses measured in seconds and placed in parentheses):

DOC: You've got, erm (0.8) bronchitis.
PAT: Er. (4.5)
DOC: ((begins to write prescription)) I'll give you antibiotics to take for a week.

This kind of sequence is a coconstruction not only of medical authority, with patients appearing to accept the physician's diagnosis without challenge, but also of the structure of the medical encounter: with no elaboration of the topic of diagnosis, the encounter moves directly to the treatment phase. Heath noted that the coconstructed brevity of the diagnosis phase of the encounter contributes to patients receiving less than optimal amounts of information about their medical conditions, which is another of the key problems identified in research in medical communication (Roter and Hall, 1992). Heath went on to show, however, that patients have their own interactional means of disagreeing with the physician's diagnosis, but disputing a diagnosis typically takes place in a different phase of the encounter, either during the treatment recommendations or the closing. Patients dispute a diagnosis by recycling the topic, repeating symptoms, emphasizing their severity, or questioning the diagnosis. In the following sequence, for example, Heath observed that the patient initially agreed with the diagnosis that his condition (angina) is the same, and the physician began to turn to treatment management, but the patient then produced an account of the recent severity of his symptoms:

DOC: It's the same as you've had all along
real[ly isn't it [with this
PAT: [Yes [Yes it is ((soft voice))
DOC: Yeah.
PAT: Only if this last couple of months it's been a bit – whether it be due to cold weather – I don't know whether that's anything to do with it.
DOC: Can I just listen in around your heart and things right?

In this sequence, the patient achieves his apparent goal of disputing the initial diagnosis; and the physician returns to the physical examination and ultimately orders more diagnostic testing. Not all recyclings of the diagnosis are successful, however, as Heath showed in the following sequence, where the physician delivered a diagnosis and the patient disputed it by offering an account of the severity of his symptoms as the physician wrote a prescription:

DOC: I'm sure Doctor Mckay's right. I'm sure these headaches yer gettin are associated with a bit of arthritis in yer – in yer neck.
PAT: It is. ((soft voice))
. . . ((physician begins writing prescription))
PAT: It's the headaches was the thing that's got me. More than anything else – More than the devil in hell because they were gettin' more or less permanent yer know
. . .
DOC: Right well I'll tell what we'll do Mister Tarett. I'll give you . . . .

In this case, the physician did not move back to the examination phase or change his original medical assessment and diagnosis of arthritis in the neck; the patient simply received the prescription being written as part of the treatment phase of the encounter. A recent special issue of the journal *TEXT* (Beach, 2001) took up the topic of diagnosis in the routine encounter in more detail, arguing for the importance of the lay diagnosis a patient might bring to the medical encounter.

The Context of the Medical Encounter

In the research literature on the discourse of the medical encounter and on the discourse of institutional encounters in general, there is an ongoing debate about how to take account of context in an analysis (Sarangi and Roberts, 1999). The linguistic anthropologist Bronislaw Malinowski originally called attention to the context of situation, defining it ethnographically as the larger sociocultural frameworks that surround language and speech events. Through the work of Dell Hymes, John Gumperz, and other linguistic anthropologists, sociolinguists, and discourse analysts, this approach works to discover and describe the complex connections between the organization of discourse and its larger social and cultural contexts, considering discourse sequences that reflect and perform gender, ethnicity, class, and the sociopolitical power and prestige of professions and institutions (Schiffrin *et al.*, 2001). Another approach that has been influential in research on the discourse of medicine defines context ethnomethodologically as the social actions participants coconstruct locally through the turn-by-turn organization of interactional sequences. Through the work of Harold Garfinkel, Erving Goffman, Emanuel Schegloff, and other conversation analysts, this approach works to discover the local management of the social and institutional order by describing how participants themselves are observably oriented to this local context, looking closely at turn-taking, turn design, lexical choice, sequence organization, structural organization, and asymmetry and accountability in professional and institutional encounters (Heritage, 1997). Both approaches are based on the close analysis of naturally occurring data, and both approaches see context as both created and reflected in discourse, particularly in institutional encounters. Both approaches have been critiqued and debated extensively. In discourse analysis, the concept of context can seem too uncontrolled: van Dijk (1997) once noted that "there is no *a priori* limit to the scope and level of what counts as relevant context," an analytic situation Michael Silverstein questioned by asking, "When is enough enough?" In conversation analysis, the concept of context can seem too narrow: Gumperz (in Sarangi and Roberts, 1999) noted that the primary focus on what is overtly present and oriented to can miss important aspects of interpretation that are more indirect but still important to understanding and interpretation, an analytic situation that does not give a complete answer to Michael Agar's question, "What is going on here?" Silverman (in Sarangi and Roberts, 1999) characterized the difference between the approaches as an emphasis on the *how* (ethnomethodological conversation analysis) in comparison to an emphasis on the *why* (ethnographic discourse analysis). An oversimplified, but perhaps useful, way to characterize these two approaches is to note that ethnographic discourse analysis focuses on the context *of* the medical encounter, with attention to the sociocultural context of situation, whereas ethnomethodological conversation analysis focuses on the context *in* the medical encounter, with attention to the observable orientation of the participants. Many researchers agree that a mixed approach to the analysis of the medical encounter is optimal, one that combines ethnographic and ethnomethodological approaches (Sarangi and Roberts, 1999); however,

there is not space to discuss fully these sometimes competing and sometimes complementary theoretical and methodological approaches of discourse analysis and conversation analysis, although this topic is taken up in a number of the references cited earlier and in other entries in this encyclopedia (for more on the discourse of the routine medical encounter, *see* **Medical Discourse: Doctor–Patient Communication; Medical Communication: Professional–Lay; Medical Discourse: Sociohistorical Construction**; for more on discourse analysis generally, including the conflicts over context, *see* **Text and Text Analysis**).

Specialty Care Medical Encounters

The research literature reviewed earlier shows that the primary care encounter in medicine is complex at a variety of levels, from the microlevel of the organization of interactional sequences to the macrolevel of coconstructing medicine as a social institution. One aspect of medicine as a profession and institution that is largely ignored in this work, however, is the distinction between primary care and specialty care. In Western medicine, as practiced in the United States and other developed countries, physicians typically complete a residency within a specialty, some of which have a primary care focus (specialties include internal medicine, family medicine, obstetrics–gynecology, pediatrics, general surgery, orthopedic surgery, emergency medicine, psychiatry), and some physicians go on to complete a fellowship within a subspecialty that has a narrower focus (internal medicine, for example, has subspecialties in cardiology, nephrology, endocrinology, gastroenterology, urology, and hematology–oncology, and others; surgery has subspecialties in neurosurgery, thoracic surgery, urology, colorectal and more). Subspecialty care focuses on particular diseases and conditions, both acute and chronic, in hospital and clinic settings, and physicians who practice in subspecialties are called specialists. [There is a systematic terminological difference between the medical and lay language of the specialty/subspecialty system. In medicine, physicians complete a residency in a specialty (internal medicine, general surgery) and may complete a fellowship in a subspecialty (medical oncology, colorectal surgery). Within this terminology, the title of this entry should perhaps be the discourse of the subspecialty encounter. In lay language, however, subspecialists are simply called specialists, and this is a terminology that physicians use in medical encounters with patients and in informal conversations with medical staff. I thus use the latter terminology here.] Patients typically enter specialty care by illness or trauma, sometimes by means of a referral from a primary care physician upon diagnosis or suspicion of diagnosis and sometimes by means of complications in an illness or hospitalization. In many instances, entry into the specialty care system of medicine is a surprise or a shock, often unwelcome and typically disorienting (*see* **Medical Discourse: Illness Narratives**). In the institutional and professional context of health care, the line between primary care and specialty care is not an absolute one. Some conditions, such as diabetes or congestive heart failure, are managed by primary care physicians as well as specialists. The line can be contested within the profession: specialists sometimes accuse primary care physicians of not referring patients to them appropriately, and primary care physicians similarly accuse specialists of stealing their patients. Access to specialty care can be contested within institutions as well: one principle of managed care in a health maintenance organization is the restricted access to consultations with specialists, not without controversy.

Within this complicated context, the discourse of the specialty care encounter is just beginning to emerge as a focus for research in linguistics, with a research agenda that has many unanswered questions: Is there a generic structure of the specialty medical encounter? How is it similar to or different from the structure of the primary care encounter? Does the structure of a specialty medical encounter differ across specialties? How are the interactional sequences within the phases of a specialty medical encounter organized? How are these organizations of interactional sequences similar to or different from the organization of sequences in primary care encounters, institutional encounters in general, and ordinary conversation? How does the discourse of a specialty care encounter reflect the context of the medical specialty? How do physicians and patients come to coconstruct the context of a medical specialty? How does research on specialty encounters contribute to knowledge about the discourse of medicine? How does research on specialty encounters contribute to improved medical communication for physicians and patients? Although research has barely begun to consider these and other questions about the specialty medical encounter, there are interesting points of comparison to the phases and sequences of the primary care medical encounter appearing in the literature, including the reason for the visit, the medical history, the understanding of diagnosis, and the treatment discussion.

The Reason for the Visit in Specialty Care Encounters

In specialty encounters, the reason for the visit, which is typically solicited from the patient with an open-ended question in the primary care encounter, appears to be organized interactionally across a series

of encounters with a focus on building an ongoing context of combined medical–lay expertise. Working from a database of 120 medical encounters between pediatric specialists and families who have a child with a disability, Barton (1996) found that in first encounters with pediatric specialists, physicians typically present the reason for the visit to families, thereby describing the particular medical problem that their specialty will manage, as in the following sequence with a pediatric neurologist:

DOC: Now the question is – The reason why you're seeing me is because of the EEG and what should we do about it.

. . .

DOC: Now I will take a look at the EEG – you know – again – just to be sure that – you know – how much of activity – of seizure-like activity was there, because the question remains whether we should treat her or not.

MOM: Um-hmm.

In this sequence, the neurologist explains *the reason why you're seeing me* in terms of the specialty of pediatric neurology, identifying its chief diagnostic tool, *the EEG*; the chief medical problem managed by neurology, *seizure-like activity* in the brain; and the treatment options within the specialty. The mother's responses in this sequence are primarily acknowledgments of the receipt of information.

Through initial encounters where physicians pay considerable interactional attention to describing their own medical specialty as the reason for the visit, families appear to develop a sophisticated lay understanding of the institutional organization and professional domains of medical specialties in the care of their child, including the relevant diagnostic tests and the treatment options for management. In follow-up visits, both physicians and families seem to orient to this construction of medical–lay expertise by organizing the sequences of this phase of the encounter in terms of the management of the specific medical condition of the specialty. Physicians sometimes retain control of the discourse of this phase of the encounter by providing the reason for the visit themselves, as in this sequence, again from pediatric neurology:

DOC: ((entering room)) So what's been happening? His last levels were pretty good. In December it was 8.8, since they increased the dose, which is where we would like to maintain him at.

MOM: OK.

DOC: Uh – so that if he's – you know – uh – we don't have – you know – at least ah – Even if he's thinking of having a seizure, that should prevent him from having one.

MOM: We haven't seen any and school hasn't reported any of them either so –

Here the physician presents the reason for the follow-up visit as treatment management, reporting the relevant test results from her review of the chart and claiming that maintaining the current level of medication should prevent the child from having seizures. The mother seems observably oriented to management of the seizure disorder as the reason for a pediatric neurology visit, providing both observed and reported information about seizure activity. Physicians do not always retain control of this phase of the encounter, however. In the following sequence, again from pediatric neurology, it is the mother who presents the reason for the current visit in terms of the specialty:

MOM: ((after physician asks the child how he is doing)) I don't know – uh – we're not sure what's going on. Um – his Depakote levels got weird, and as they got weird, he increasingly got hyper. When – when you added the other Depakote, for about four days he – the hyper was gone again. It's starting to come back. I'm wondering if his levels are not too high.

Here the mother gives her impression of the levels of antiseizure medication first and then introduces her concern about its possible side effects. Experienced families thus routinely orient to the domain of the specialty when they initiate this phase of the encounter in follow-up visits.

It appears, then, that specialists do interactional work to orient families to the domain of the specialty in initial encounters, and then physicians and families orient to this construction of medical–lay expertise in follow-up visits. With this orientation to the domain of the specialty, the encounter can be coconstructed as problem driven in terms of the specialty, with foregrounded attention to treatment management. This joint focus on a particular problem and its course of treatment in the specialty encounter is somewhat different from the open-ended focus on the patient's chief complaint in the primary care encounter (see the recent special issue of *Research on Language and Social Interaction* (Candlin and Candlin, 2002) on expertise in a variety of health-care encounters).

It is also of note here that specialty encounters seem to have an interactional orientation toward a series of encounters in an ongoing physician–patient/family relationship. Ainsworth-Vaughn (1998) pointed out that the context of an established relationship can significantly affect the discourse of medical encounters. In comparison to the studies of primary care mentioned earlier, where patients asked few questions

(West, 1984; Frankel, 1990), Ainsworth-Vaughn's study of encounters within the specialty of medical oncology found that patients ask significantly more questions – almost 40% of the questions were asked by patients in a set of 40 encounters balanced for gender of patient and physician. Ainsworth-Vaughn argued that the context of established relationships allows both physicians and patients to claim power in the discourse of the encounter, with power defined not only as control over the emerging discourse but also as control over medical decision making. Silverman (1987) similarly noted that question–answer sequences seem to reflect the course of treatment within specialty medical care. In his study of cardiologists and parents of children with heart conditions, he found that parents ask different kinds and different numbers of questions at different points in the child's course – before treatment, after diagnostic catheterization, and after surgery. In his study of adolescents in diabetes clinics, Silverman (1993) found that physicians and patients developed a more negotiated style of interaction as the relationships become more established and physicians extend more autonomy to teenage patients in the management of their diabetes.

The Medical History in Specialty Care Encounters

In medical encounters, question–answer sequences are particularly prominent in the history phase. In the primary care encounter, the medical history typically elicits patients' own reports of their past illnesses and present symptoms. The medical history in the specialty care encounter, however, also reflects the complex and ongoing context of specialty care. Barton (2000) noted that children with disabilities are routinely seen by multiple specialists, including a developmental pediatrician, a neurologist, an orthopedist, a physiatrist, a gastroenterologist, an ENT, an ophthalmologist, and more. Families move back and forth among specialists in a complex web of referrals and visits for attention to new or ongoing medical problems and conditions, a situation that is sometimes criticized as an unfortunate fragmentation of medical care. This expanded context of care is reflected in the medical history, where families are often asked to provide accounts of their encounters with other pediatric specialists, as in the following sequence:

DOC: Who sees him, Dr. L or Dr. B?
Mom: Dr. L.
DOC: And what does Dr. L say? The last time you saw him.
MOM: His X-rays came out just fine.

The specific specialty (orthopedics) is not even mentioned here, but when asked for an account of *what does Dr. L say*, the mother answers in terms of her lay expertise, citing evidence from the primary diagnostic tool of orthopedics (*X-rays*) in order to report that the child is *just fine*. When families deliver what the physician apparently judges to be a competent account of a referral with an appropriate construct of lay expertise, like the one given, the history moves along smoothly, and parents' accounts can become the basis for decision making.

When families deliver a more problematic account of a referral in the history, however, one that does not reflect an appropriate construct of lay expertise from a medical perspective, interactional problems arise that can affect the relationship between the family and the physician as well as the medical decision making. In the following sequence with a developmental pediatrician, for example, the family is asked for an account of their child's visit with the ENT (in the following sequence, the term *stridor* refers to a harsh vibrating sound during breathing due to obstruction of the air passages):

DOC: Now, does he see the ear, nose and throat doctor still?
MOM: Um-hmm.
DOC: Who does he see?
MOM: Uh, Dr. N. Paul N.
DOC: Do they think that he may outgrow some of this stridor too, with time?
MOM: Yeah.
DOC: [OK.
DAD: [I do. I don't know what the doctors say, but I know he is. Unless there's so many kids who have the signs that he has, but he is so much like a normal child. It's just that his muscles, it's going to take time to – to develop. Right now, to me, he's at a stage that a eight month old baby would be at.
DOC: [Uh-huh.
DAD: [And see, I'm looking at it like that's going to take time. By the time he five or six, he going to be able to talk. He going to be able to crawl, he going to [be –
DOC: [At school with the right interventions, he may be able to do some of those things. We'll have to see. ((change to motherese voice)) Who's on your bib there sweetie?

In this sequence, the physician's question asking for the ENT's opinion is designed for either a brief *yes*-answer or else a longer *no*-answer with elaboration. The mother provides the optimal *yeah* answer, and the physician acknowledges it with an *OK*, but the father speaks at the same time to offer a lengthy diagnostic and prognostic description of the child. His account, however, is problematic with respect to a combined medical–lay expertise based on knowledge of and experience in the specialty medicine

system: his *I do* is not backed up either by an account of a medical visit with another specialist or an account demonstrating substantive lay expertise, because his description is in conflict with the medical prognosis for his severely impaired child. The developmentalist gives him no encouragement to continue this problematic account, providing only one minimal back-channel and then abruptly interrupting to end the father's talk by addressing the nonverbal child in the pitch and patterns of motherese. The father's account is asymmetrically received here, and his contribution is completely ignored by the physician. Later in the encounter, the father expressed considerable dissatisfaction with the visit to the Child Care Clinic, criticizing the staff for "asking the same questions," and after the encounter, the staff expressed considerable disdain for the father's perceived ignorance about the actual condition of his child. In this case, the interactional trouble contributed to the increasingly adversarial relationship between the medical staff and the family that ultimately moved to hierarchical decision making by the staff without incorporating the contributions and concerns of the family (this encounter is discussed in more detail in Barton, 1999, 2000).

The Understanding of Diagnosis in Specialty Care Encounters

As the excerpts and discussion earlier indicate, lay expertise in the domain of a medical specialty encompasses a number of aspects, including diagnosis, prognosis, and treatment management of a medical problem or condition. Understanding of diagnosis, however, is a particularly important aspect of specialty medical care, and the delivery of diagnostic news is constructed very carefully by medical professionals in specialty encounters. Maynard (1992, 2003) has worked extensively on the delivery of diagnostic news in both primary and specialty encounters. Based on fieldwork in clinics for the evaluation of developmental disabilities in children, Maynard (1992) identified the perspective-display sequence as a crucial means by which specialists create alignment to the medical view of a diagnosis. A perspective–display sequence first asks the parents for their view of the child, which, if the view is in alignment with the medical diagnosis, allows the professionals to agree with the parents on the diagnosis, as in the following sequence:

DOC: What do you see? As – as his difficulty.
MOM: Mainly his uhm – the fact that he doesn't understand everything and also the fact that his speech is very hard to understand what he's saying lot[s of time
DOC: [Right
. . .
DOC: Okay. I – you know we basically in some ways agree with you insofar as we think that Dan's main problem you know does involve you know language

A perspective–display sequence thus coimplicates agreement between the parents and the specialists on the diagnosis of the child, which interactionally constructs alignment as the basis for the rest of the encounter. Maynard noted that medical specialists sometimes have to do considerable interactional work to bring about this alignment; in the following sequence, for example, the physician reformulates the mother's description of her daughter:

MOM: . . . and I have seen no progress, from September to June. For her learning ability, she is slow.
DOC: That's what we uh also found on – on psychological testing. That she was per- not performing like a normal uh six and a half year old uh should.
MOM: Mm-hmm.
DOC: And that she was performing more uh what we call as a borderline rate of retardation.

The physician here initially agrees with the mother that *that's what we also found on psychological testing*, but he interactionally reformulates and upgrades *slow* from *not performing like a normal six and a half year old* to *what we call as a borderline rate of retardation*. Through perspective–display sequences and their elaboration and development, medical specialists work to coimplicate a problematic diagnosis that brings participants into alignment. Maynard noted that the perspective display sequence can create alignment nonproblematically or problematically, as shown in the contrasting sequences above, although he argued that it is ultimately the medical view that becomes the official diagnosis for the child.

The Treatment Discussion in Specialty Care Encounters

There has been relatively little research on the treatment phase of the medical encounter, either in primary care or in specialty care. Barton (2004) looked at treatment discussions in medical oncology encounters, describing the structure within this phase as having four parts: first, foregrounding the relevant diagnostic information; second, presenting treatment information; third, asking and answering questions; and fourth, arranging treatment logistics. Using Erving Goffman's distinction between the front-stage and back-stage of institutional encounters, Barton also noted a systematic difference in prognosis as a

topic. On the front-stage with patients and families, prognosis is an unstable topic, not always a predictable part of the treatment discussion, and a topic that is often interactionally elided and backgrounded in indirect language, as in the following sequence:

DOC: When they did the liver biopsy in March, it showed that there were multiple lesions of the liver. And that means that we can't cut it out. It has to be treated by some sort of chemotherapy to try to control it. Now, we have a number of different drugs that we use for that kind of treatment.

Here, the information on *multiple lesions of the liver*, which *means that we can't cut it out* does not explicitly state the diagnosis of widely metastasized cancer, nor the prognosis of incurable disease that will run a fatal course. Further, the treatment recommendation (*it has to be treated by some sort of chemotherapy*) ends with the euphemistic expression *to try to control it*, an expression that does not explicitly note that treatment will ultimately fail. In the back-stage talk immediately after this encounter, the physician and researcher had the following exchange:

RES: Sweet lady.
DOC: Bad disease.
RES: Because they didn't catch it before it went to the liver?
DOC: Yeah . . . . She's an older, frail lady. But she has bad disease.

On the back-stage with medical colleagues and even researchers, prognosis is a predictable topic, especially in cases of expected negative outcomes, and a topic that is foregrounded with direct language in the talk of insiders (in the back-stage discourse of medicine, the expression *bad disease* carries the implications of incurable, fatal disease). Barton suggested that the front-stage presentation of prognosis is organized to preserve hope for the patient and the family, whereas the back-stage discussion of prognosis is organized to reflect the preponderance of negative experience in medical oncology and its and its resultant frustration.

In another study of treatment discussions, Barton *et al*. (2005) looked at a set of end-of-life discussions in a surgical care unit, where the aim of the discussion is to change the goals of treatment from aggressive measures aimed at cure to palliative measures aimed at comfort. The structure of this discussion has four parts: first, openings, in which physicians as well as families coconstruct the traditional role structure of a medical encounter, with the physician in the interactional and decision-making lead; second, description of current status, in which physicians present medical information leading to a summary statement that implies that the patient's status is terminal; third, decision making, in which a holistic decision to end life support is made indirectly and inferentially; and fourth, logistics of dying in the ICU, where physicians and families discuss the details of death and dying. Barton *et al*. argue that the description of current status is actually the crucial part of the end-of-life discussion, because it is here that physicians and families, through an inferential summary statement, interactionally establish a consensus that the patient is dying, which makes it reasonable that continuing further treatment, including life support, would be futile and only prolong the patient's suffering, as in the following decision-making sequence:

FAM: The body is in shock because of the infection.
DOC: So that's where we are. I am absolutely sure that you've had discussions and discussions among yourselves and other family members . . . . What I'd like to do now would be to open up the discussion with regards to the thoughts that people have had or any unanimity or is there any unanimous opinion with regard to what you think she might want under these conditions. Have you had a chance to talk about this?
FAM: Yes. If I – I don't think she would want it.
DOC: I know I can remember she told me once, you know, she wouldn't want it, because if she felt like they cut on her once, they would continue to cut, and I don't think she would want it.
FAM: We all agree.

Here, the family's acknowledgment that *the body is in shock because of the infection* allows the physician to sum matters up again (*so that's where we are*) and then move to the frame of decision making as *what she might want under these conditions*. The family then seems to make a holistic and inferential decision to withdraw futile life support by saying that *she wouldn't want it*. Barton *et al*. note that the description of current status and the decision-making sequences use language drawn from the indirect discourse of death and dying in ordinary language (as in the family's use of the antecedentless pronoun *it*), but one of the functions of the fourth and final part of the discussion is to develop a more medical discourse of death by making specific the inferences of terminal status and the decision to withdraw life support in a combined medical–lay discourse that situates death more technically within the process of palliative care. In the earlier discussion, for example, the physician specified that *we have a protocol, a set of rules we follow to keep people so sedated that they would not feel any discomfort*.

However, in discussions where there is no interactional consensus on the patient's status, decision

making to end life support does not take place, as in this sequence:

DOC: So when someone in the – experiences all of these, um, complications of the sepsis in the face of the strong medications that we are using, um, we feel like it is important to try to touch base with the family and clarify the goals of treatment and what you imagined the goals of treating her to be.
FAM: OK.
((silence))
DOC: Does that make sense? What questions can I answer to help that make sense?
((silence))

Here, the physician sums up the patient's terminal condition as *complications of the sepsis* and tries to move to the frame of decision making, but the family member's *OK* seems to be more of an acceptance of the topic of treatment goals rather than an acknowledgment or agreement with the inference offered by the physician's summary statement. With no uptake of her summary statement or her move to decision making, the physician resorts to asking whether there are any questions. With her continued silence, however, the family member provides no interactional indication of alignment, and the discussion falters.

Future Research on Specialty Care Encounters

From the literature reviewed, it appears that the general structure of a specialty care encounter is roughly similar to the structure of a primary care encounter, with similar phases – opening, reason for the visit, history and physical, treatment discussion, and closing. The specialty encounter, however, is problem driven in terms of the domain of the specialty – the medical condition it manages with its diagnostic tools and treatment options – within a complex context of medical–lay expertise created through multiple encounters in an ongoing physician–patient relationship. In comparison to the primary care encounter, the interactional sequences within the phases appear to be organized with respect to this context of expertise in the specialty care encounter: the reason for the visit is interactionally constructed in terms of the specialty, initially by physicians and subsequently by families; the history draws on accounts of care within the specialty medical system, which displays the family's expertise in this context; and the understanding of diagnosis appears crucially important, with considerable interactional attention to creating alignment between specialists and families. Perhaps reflecting the focus on managing medical problems and conditions, the treatment discussion appears to display considerable variation across specialties, with complex internal structures for different kinds of discussions. Although research in this area is just beginning, it is based on an important question for linguistic research on the discourse of medicine: How do physicians, patients, and families coconstruct the professional and institutional discourse of specialty care?

Medical Writing, Revising and Editing

M Pilegaard, Aarhus School of Business, Aarhus, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Background

Medical writing, editing, and revision is an emerging field in linguistic research and a thriving field in linguistic practice. It falls between several different disciplines, linguistic as well as nonlinguistic, and enjoys the attention of both medical and linguistic communities of interest. The medical discourse communities began to take interest in the linguistic quality of papers in the late 1980s with the growing globalization of research. The international nature of the readership requires that research should be written clearly and concisely and the need for better quality in medical communication is now widely recognized and has given rise to a growing number of suggestions, checklists, and guidelines for quality improvements targeting the structure, style, and rhetoric of medical communication.

This globalization does not imply that all researchers have equal access to publication. There is considerable cultural bias with about 95% of all papers published in English coming from the Western, particularly Anglo-American, industrialized countries (Gibbs, 1995) and a preference for U.S.-based articles in U.S.-based journals (Link, 1998).

Medical approaches to medical writing, revision, and editing center on the issues of uniformity of structure and clarity, precision and economy of language, and the need to ease non-native English speakers' access to international publication. Linguistic approaches are varied and draw on disciplines such as genre theory, functional sentence analysis, and contrastive linguistics. Genre theory, which is concerned with global linguistic patterns that have developed in a linguistic community for fulfilling specific communicative tasks in specific situations, has provided particularly useful insights into medical text genres by creating a link between purpose at various levels of discourse and the situationally appropriate choice of linguistic means with which to realize these purposes. This article focuses mainly on the genre of the medical research paper.

Medical Writing

Medical writing serves different purposes. The medical textbook, for example, covers a range of topics, whereas the traditional medical paper is more focused. Most journal articles are designed to disseminate the results of a discrete topic of inquiry. Apart from honesty in reporting the results of the study, the most important element in medical scientific writing is clarity: the reader should be told why the study was performed (introduction), what the research question is (introduction), what was done (material and method), what was found (results) and what the results mean (discussion). To enforce this presentation style – known as the IMRaD structure – medical journals require that papers are divided into text sections with uniform headings serving the above purposes. This uniform style is described in *Uniform requirements for manuscripts submitted to biomedical journals* and the Council of Biology Editors' manuals of style.

General Rules of Medical Writing

General rules of medical writing increasingly mirror the advice of a group of editors of medical journals who first met informally in Vancouver in 1978 to establish guidelines for the format of manuscripts submitted to their journals. This group is known as the Vancouver Group. The requirements were first published in 1978. The group is now known as the International Committee of Medical Journal Editors. More than 500 journals agree to use their *Uniform requirements*, the so-called Vancouver style, which are instructions to authors on how to prepare manuscripts, not to editors on publication style. So authors must also follow the instructions to authors in the journal as to what topics are suitable for that journal and what types of papers may be submitted. The journal's instructions are likely to contain requirements unique to that journal, such as the number of copies of a manuscript, acceptable language, size of articles and approved abbreviations, among others. The home page of the Mulford Library of the Medical College of Ohio provides links to instructions to authors for over 3500 journals in the health and life sciences.

Specific Rules of Medical Writing

Specific rules of medical writing are formulated by the individual professional communities, which set up guidelines to be followed for the production of particular text genres. These guidelines are sometimes based on empirical studies of the qualities and shortcomings of such genres. For example, evidence that the quality of reporting of randomized, controlled trials (RCTs) was suboptimal initiated the development of consolidated standards of RCT (CONSORT) reporting by a group of scientists and editors. The objective of CONSORT is to facilitate critical appraisal and interpretation of RCTs by providing guidance to authors about how to report their trials. A revised CONSORT statement has recently been issued with checklist items for the contents of the title, abstract, introduction, methods, results, and discussion and with accompanying flow diagrams depicting information from four stages of a trial: enrolment, intervention allocation, follow-up, and analysis. The statement is available on the Internet, and it includes text examples, for instance on the generalizability (external validity) of trial findings from which valuable linguistic information may be derived.

The case for structure in scientific papers is made not only for the macro level, but also for the micro level (i.e., what linguists would call the move or step structure). Thus, most abstracts are highly structured and certain prestigious journals advocate a specific structure even for the discussion; for instance, the *British Medical Journal* suggests that the discussion should be structured as follows:

- statement of principal findings
- strengths and weaknesses of the study
- strengths and weaknesses in relation to other studies

- meaning of the study: mechanisms and implications for clinicians and policy makers
- unanswered questions and future research.

Reviews are also expected to be written according to specific guidelines. An analysis of reviews included in the Cochrane Library, a regularly updated collection of evidence-based medicine databases, showed that a sample of Cochrane reviews had problems in terms of both structure and style. Hence, stylistic problems were encountered in 23% of 53 Cochrane reviews published during 1998. The stylistic problems included many spelling, grammatical, and typographical errors, and reviewers' comments contained statements like "seems to be an unfinished draft," "needs to be edited to be more readable and comprehensible" (Olsen, 1998). Cochrane reviews are, on average, more systematic and less biased than other systematic reviews, and the linguistic flaws have a negative effect on the validity of the scientific contents communicated.

Medical Editing

Medical editing and medical revision are two sides of the same coin. Their domains may be visualized as overlapping circles. Editing is concerned mainly with the contents of the text. The most important thing in the editing process is to check the validity, i.e., the extent to which the study suffers from bias or errors. A common error is for example to confuse no evidence of effect with evidence of no effect. Editing also seeks to answer the major weaknesses of the paper; in particular, whether the manuscript requires additional work in terms of originality and importance, adequacy of design or approach, adequacy of materials studied, accuracy of interpretation of results, statistical analysis, relevance of discussion, soundness of conclusion, appropriateness of references, tables, and figures, or clarity of presentation. A good rule is to shorten the introduction and discussion and to lengthen the methods and results. Half the manuscripts submitted to the *British Medical Journal*, for example, are rejected for lack of importance to a general medical audience, serious scientific flaws, or lack of originality.

Editing is often achieved through so-called peer reviews, which denotes a number of processes, most commonly the gathering of opinion on the quality of the paper from other experts, either in-house or external experts. The review process starts when a manuscript is received at the editorial office. There are generally two kinds of review systems: the 'board review,' where all reviewers are members of an editorial board, or 'pool reviews,' where the editorial board draws on a pool of expert reviewers. Most journals have developed their own review strategies, but generally reviewers receive review forms, instructions and occasionally associated materials like instructions to authors and sample reviews. The reviewers are usually asked to provide text comments detailing their critique and suggestions (Shea *et al.*, 2001).

Medical Revision

Text revision is used here not in the traditional sense in English of modification of the text for contents, but in a narrower sense of reviewing, editing and proofreading with a focus on the form and style of the text. Revision incorporates the checking of the macrostructure and microstructure of the text, language and style issues, and judging suitability for the target reader or client. It embraces both the monolingual editing that borders on technical editing and, where translators and language revisers are included, the checking of the target text against the source for accuracy, style, and register.

Revision ideally falls into three steps. The first step is to make sure that the manuscript is written according to the general guidelines set out in *Uniform requirements* and the specific instructions to authors on how to prepare manuscripts. It must follow the target journal's format for style. Most journals, for example, spell out numbers less than ten, unless they appear with percentages or units of time or measure, and most but not all use upper-case P for 'P values' and C for 'Chi-square,' but not all.

The second step is to revise for structure, i.e., to ascertain that the move and step structure of the text serves the purpose of the text maximally, both at the overall (macro) level and at deeper (micro) levels. This can be done first by analyzing the move structure of the text section by section, second by comparing the move structure with the prototypical move structure for the genre in question (e.g., the IMRaD structure), and, third, by revising the move structure where necessary to achieve model fit. The aim is to make sure that the 'superficial' levels of argumentation or the types of argument that lie in each section of the text are supported by the 'deep levels' of argument, viz the persuasive power of each sentence, which depends on elements such as use of active or passive, the position of adverbs and adjectives, the use of *if*-conditionals, hedges, and other forms of modality.

The third step in the revision process is to analyze the text for correctness of grammar (active/passive, subject–verb agreement, position of modifiers, dangling participles, correct use of tense), word choice (jargon, bias-free language, good verb choice), and correctness of spelling and punctuation. This stage

should also include checking all other rules of good English usage, including avoiding starting sentences with such phrases as 'it has been shown that,' 'it was found that,' 'based on the fact that' (change to 'because'), and with 'there' (as 'There has been an increase in the number of patients' [change to 'More patients are'] and 'There is evidence to suggest that those who cease smoking' [change to 'Those who cease smoking may']).

Finally, where the target text is produced in a foreign language, it is necessary to check for source language interference at levels of lexis (word level), syntax (sentence structure, sender–receiver relationship), and text (cohesion/coherence).

Introduction

This article summarizes work that addresses the ways in which the practice of medicine is changing; how these changes are affecting medical discourse, and how they point to medical discourse becoming increasingly dependent on and coconstituted by what may be seen as 'nonmedical' discourses. In reviewing this work on the changing status of medicine in contemporary societies, this article emphasizes medicine's dependence on and accountability to nonmedical professionals, such as nurses, allied health clinicians, administrators, policy makers, managers, information technology specialists, and, last but by no means least, health care 'consumers' and their caregivers. The article makes the point that medical discourse is no longer appropriately studied *in vacuo*. Although medical talk may still occur in settings where we find

doctors interacting with patients or other doctors, and although medical writing still answers to the demands of disciplinary specialization, this article takes issue with analysts of discourse rendering invisible medical dependencies on other professional and nonprofessional voices and practices by constructing them as merely contextual, taken-for-granted, and therefore marginal to the analysis of medical language and discourse 'proper.'

Before setting this argument out in greater detail, let me illustrate some of these dependencies with an example. Consider the segment of medical discourse below. It is part of what is called a 'critical incident report' (CIR), a form used to report events that are judged to be 'out of order.' This segment was written by a doctor who was in charge of moving a patient from a rural to a tertiary hospital setting. The doctor wrote the report because he found that something was amiss with the way the patient had been treated by the other doctors (the patient had been intubated incorrectly) and felt that this unduly hastened the patient's death. A CIR, then, is an organizational device by means of which clinicians communicate about adverse or critical events in order to learn from such events and prevent them in the future. The headings are standard in the free text portion of the critical incident form.

> **Story**
> Patient with severe [internal] bleed. GCS 4 on admission. Intubated by doctor in Emergency Department. Left spontaneously breathing. Retrieval team arrived. Breath sounds heard within usual total assessment. Readied for transfer, paralysed for transport. Subsequent demise, presumed to be of neurological cause. Later review of CXR (not looked at by retrieval team) showed ETT in oesophagus.
> **Outcome**
> Cardiac arrest.
> **Steps Taken or Treatment Required**
> As presumed to be neurological cause, patient already elderly and moribund, aggressive resuscitation not attempted.
> **Was This Incident Preventable?**
> Yes – always check CXR when available, re-check airway if paralysing.

For those interested in medical discourse, this brief text is rich for a range of reasons. First, there is a degree of mimesis between the criticality of the event and its multiple acronyms (its abbreviated semantics) and its staccato syntax. In that sense, the CIR is reminiscent of the medical chart or the patient medical record produced in hospitals. Second, the text is a standardized 'genre,' insofar as critical incident reporting has crystallized as a particular textual construct across various types of organizations. Yet this genre is complex, as it is a curious combination of narrative fragments: *Story* (what happened), *Steps Taken* (what did you do), as well as more technical components: *Outcome* (an assessment about what this incident produced), and *Was This Incident Preventable?* (a judgment about how avoidable the event was). Genre as 'standardized meaning making ritual' has been deployed as a perspective for making sense of medical discourse, but largely only in relation to traditional constructs such as dyadic medical consultations, medical notes, monodisciplinary ward rounds, and 'case presentations.'

Yet another dimension of the text is its context. Context is commonly mentioned in analyses such as those cited above but remains little explored on the assumption that it merely enables the production of the text that is the ultimate focus of attention. From the CIR above, however, it is evident that it was the considerable contextual or **organizational** complexity that played an important role in bringing about the occurrence described and in producing the CIR in the first place. We can go further than this and conclude from the introduction of CIRs into medicine more generally that it is clinical–organizational complexity that is increasingly at the heart of medical work, to the point where all kinds of new genres and discourses are now seen to be necessary to handle these organizationally complex facets of medicine.

As one among a number of such emergent discourses in and around medicine (such as clinical guidelines, clinical benchmarks, and so on), this critical incident report provides a means to reflect on how the work performed by people in one department affects what others do elsewhere, whether clinical documentation and communication facilitate such care trajectories, how other professionals fit into them, and whether adverse events arise as a consequence of care trajectories' lack of explicit, proactive organization. The CIR as discourse phenomenon thus enables reflection on the changing nature of medicine more broadly and on how emergent medical genres and discourses now increasingly serve to foreground the integration of medicine with those alternative dimensions of patient care on which it increasingly depends: information and communication technologies; medical scientific evidence and treatment guidelines that are continually updated; patient and family preferences, concerns, and complaints; proactive interfacing of medicine with nursing and allied health practices, and so forth.

Perhaps the dearth of linguistic attention to these contextual-organizational dimensions of medicine can be explained by pointing to the intimate sociological knowledge of situated medical practice that it requires. As Cicourel noted many years ago,

> Participants of discourse or readers of a text are always engaged in selective use of the information that they can attend to. Limited capacity processing constraints imposed by a complex setting and the participants' knowledge base can sharply reduce the participants' comprehension of what is taking place. The researcher faces similar problems. We normally examine single utterances or connected discourse that run for a few lines, giving careful attention to lexical items, pronominal usage and repetition, the repetition of clauses that give referential prominence to a person, object or event, WH-cleft constructions, IT-cleft constructions, relative clauses, rhetorical questions, and the like; yet we may avoid or be unaware of information that presupposes organizational constraints and complex social relationships that can be obtained only by ethnographic field research. (Cicourel, 1982: 53)

We could say that we are interested only in the linguistic details of specific people's discourse practices and not in the multivariate complexities that professionals confront when faced with **organizing** their expert work with others. This article suggests, however, that downplaying 'organizational constraints' as pointed to by Cicourel poses not just an analytical problem, but also a political quandary. Much linguistic analysis has delineated medical discourse in such a way as to conform with and thereby reinforce medicine's own preferred self-image as an autonomous profession accountable only to itself – an image that in current circumstances is not just becoming unrepresentative of what medicine does, but also untenable in view of contemporary ethics.

It is on those grounds that this article seeks to shift the spotlight toward research that has investigated the 'conditions of possibility' of medicine; that is, the organizational and professional practices that in effect afford the execution of medicine. The article profiles a body of research that operates on the interstices of a number of disciplines (linguistics, discourse analysis, health services research, nursing research, medical sociology, and clinical ethnography) and that questions the view of medicine as 'discourse of all discourses.'

The research reviewed here challenges the closure that medicine itself imposes on what medicine is and does, and it defines its object of research in a way that exceeds the boundaries currently observed by the majority of linguistic and discourse studies of medical language. If we ask how have the linguistic sciences constituted medicine as their object to date, we could start with perusing the contents of prominent publications associated with the disciplines of linguistics and discourse analysis: *Journal of Sociolinguistics*, *Journal of Pragmatics, Discourse and Society, Discourse Studies, Text, Research on Language and Social Interaction*, as well as overview publications such as the *Handbook of linguistics, Sociolinguistics: An international handbook of the science of society*, the *Handbook of pragmatics*, the *Handbook of discourse analysis*, or more specialized collections of papers such as *The construction of professional discourse* (Gunnarson *et al.*, 1997), *Talk, work and the institutional order* (Sarangi and Roberts, 1999) and *Talk at work* (Drew and Heritage, 1992).

What confronts us in our survey is a dearth of work on health care discourse and practice generally. In addition, we notice an emphasis on doctor talk, whether with patients or about patients. Then, of course, there are specialized domains such as 'clinical linguistics,' which centers on language disorders and speech pathology; a domain of analysis concerned with medical records and clinical documentation; a field of study that targets medical scientific discourse, its metaphors, and its technicalities; and one that considers the representation of health and medicine in the public domain. The literature further reveals that there is research on **intraprofessional** or doctor–doctor communication, but considerably less that systematically addresses **interprofessional** communication (doctors talking to nurses or allied health clinicians). There is even less research that addresses more complex stakeholder configurations involving interactions between doctors and health care managers, health policy makers, special interest groups, or community representatives. Little to no research targets the practices and discourses of health organizational change.

This article problematizes these cut-off points inherent in the distinctions that the research just cited brings to bear on the study of medicine and medical practice. It does so in two ways. First, it points to evidence that modern medicine is now so complex that the distinctions just reviewed are increasingly difficult to maintain epistemologically and ontologically, and therefore analytically. Second, this article reviews work on medical discourse that has operated in the margins of existing research, by addressing the multidisciplinary, organizational, and technological dimensions of health care provision through which and thanks to which medicine is increasingly being reconfigured.

To realize these two aims, this article first presents a sketch of the complexity of 21st century Western health care by teasing out how the relationships between medicine, the other health professions, the State, the public, and policy have changed over the past 30 or so years. Second, and as presaged above, the article considers work that has begun to extend beyond established analytical parameters, in ways that do not delimit medical discourse and communication purely within the doctor–patient dyad, the

technicalities of medical notation, or the peculiarities of medical science. This alternative work approaches medicine from a more 'ecological' perspective to encompass increasingly pervasive features of medical discourse and practice, such as team communication, multidisciplinary procedure mapping and treatment execution, risk management and practice review processes, organizational coordination and management, information technology and electronic drug prescribing, test ordering, computerized patients records, and so forth.

21st Century Medicine: Social, Cultural, Political, Economic, and Organizational Complexities

For some, questions may remain about why we as linguists who are interested in the study of the languages of medicine need to concern ourselves with the ways in which medical practices have changed over the past three or four decades. Is there any basic change to the fact that individual doctors predominantly treat and communicate with individual patients and caregivers? Aren't hospitals much the same wherever we go, give or take a few new technologies and drugs, with similar medical specialties, common dress and uniform codes, analogous ward divisions and nursing populations, and related forms of administration and management? Even if there is evidence of medical subspecialization, organizational restructuring, and some task shifting between nursing and medicine, can it not be said that the same medicine – whether practiced as doctor talk or as medical writing – is still the mainstay of medical care? We can put this more assertively and say that, given the growing technological sophistication of medicine, its growing control over the boundary between life and death, and the increasingly multicultural constitution of medicine's client base, should we not set **more** store by understanding how doctors (are to) communicate with their patients and with one another and by clarifying how the discourse of medical science is unfolding?

Of course, the importance of work that has focused on illuminating the social values that underpin doctor–patient communication, medical professional communication, and historical or other aspects of medical discourse is incontestable. These initiatives are important for locating medicine as specialized practice in modern society. But part of this picture should be analytical attention paid to the changing face of medicine and to the implications of these changes for the practising doctor.

As part of illuminating the changes in medicine in contemporary society, we need not go back more than approximately 30 years. Medicine's pre-1970 history is far from irrelevant here, but suffice to say that, despite its heterogeneous origins, medicine gained a solid foothold in many industrialized and industrializing nation states in the course of the 20th century, combining science, specialized education and certification procedures, public institutionalization, and commercial investment. As a result of state support and institutionalization in the form of public hospitals, medicine was able to provide increasingly sophisticated treatments to growing numbers of people. These treatments forced up public investment and insurance, but medicine did little to manage its practices or its expenditures. Medicine's 'rise and rise' was slowed somewhat with the advent of the 1970s, when, as a consequence of the oil crisis and other socioeconomic pressures, its profligacy with public monies was gradually called into question. The close of the 20th century has seen medicine coming under further pressure due to a number of events that shook public confidence in its ability to control and maintain its members' standards of practice. Reports of serious medical failures in the United States, the United Kingdom, and Australia, in addition to findings suggesting that medical practice commonly results in approximately 10% of patients incurring injuries and deaths, raise critical questions about the trust and hope that societies have invested in doctors to act as people who practise medical science for the benefit of their patients in rational, expert, and judicious ways.

The importance of these developments for linguistics and discourse analysts lies in the change of status that medicine has had to confront over the last two to three decades in most countries. Clearly, the autonomy and status built up by medical professionals during most of the 20th century have not just begun to be questioned but also eroded. In even the most routine facets of medical practice, doctors are affected by a host of constraining influences such as guidelines, clinical pathways, policies encouraging multidisciplinary approaches to teamwork, resource utilization checks, lengthy hospital accreditation surveys, 'clinical pertinence' reviews (which focus on whether medical records are properly filled out), practice guidelines, and so on. Furthermore, analyses of medical discourse can no longer ignore the interests, involvements, or influences of alternative stakeholders, even if they are not always physically copresent in the consultation room, on the ward, or in the laboratory.

These stakeholders have made an indelible mark on the profile of medical discourse and practice, by requiring doctors to engage in 'informed consent' procedures (ensuring that patients are aware of the

implications of treatments provided); 'critical incident reporting and monitoring,' 'root cause analysis' processes, complaints commissions' inquiries, health care consumer organizations' initiatives, nursing unions' requirements for practice standardization and for nurses to increase their skills or cross-train, policy makers' and medical colleges' guidelines as to how to dispense medical services and treatments, managements' directives with regard to resource expenditure and budget cuts, patients' families' requests for extended care or special drugs, litigants' legal claims following substandard care, Internet group campaigns for the legalization of specific drugs, issue groups' objections to genetic predetermination and experimentation, pharmaceutical companies' pressure to prescribe brand-name drugs in place of their generic counterparts, and so on. In view of the impact of these phenomena on daily medical practice and the stresses that they cause for many doctors, it would be amiss for analysts interested in medical discourse to portray it as if these constraining influences remained peripheral to what doctors do and say, or without consequences for who they talk to and what they write about.

Put more succinctly, contemporary medical discourse, whether spoken by the single doctor to a single patient or produced during a critical incident review procedure, is *überhaupt* ('always already') shot through with multiple competing interests. In this day and age, medicine consults, diagnoses, and researches in a 'crowded space.' In addition to being inevitable in the modern-day hospital, medical discourse that creates a space for different disciplinary and stakeholder views is central to producing good medical outcomes. In reality and in practice, then, medicine is fast becoming one voice among a host of others, offering one set of expertise and relying on others for different and complementary views, knowledge, and insights. The question that arises at this point is whether there is research that has addressed any of the linguistic-discursive characteristics of these emergent facets of modern medicine.

Linguistic and Discourse Studies of Medicine as Crowded Space

As should now be more than evident, the view put forth in this article is that linguistic and discourse research needs to investigate medical language and communication so as to capture the 'crowded clinical spaces' in which it is enacted. This is not only crucial for doing justice to the complexity of contemporary medical discourse, it also prevents us from becoming unwitting players in the struggle over the changing definition of 'profession' in medicine and from finding ourselves on the side of a medicine that tries to defend its traditional boundaries in the face of inevitable reform (Dent, 1998).

Let us turn then to an overview of a heterogeneous body of work that confronts medical language and communication in a way that cuts across the neat confines of interactions occurring between doctors and patients or among doctors themselves. This body of work sets store by whether and how interprofessional and organizational coordination and communication are achieved, maintained, and, in some cases, enhanced. A good number of the investigations cited pay little attention to the linguistic details of medical representation, whereas in those that do, technical linguistic-interactive constructs, such as turn-taking, topicalization, hedging, and coherence, and so forth, have become subjugated to the need to answer questions about intraprofessional and interprofessional practices and processes (Cicourel, 1987: 220).

It is important to begin, then, with acknowledging that a considerable amount of work on intra- and interprofessional clinical communication has been performed in disciplines that are not concerned with producing linguistic or discourse analytical findings. This includes work of a more instrumental or solution-oriented sort as well as (critical) sociological, anthropological, and ethnographic enquiries. Such studies are important, even if judged from a linguistic perspective they provide little insight into the syntactic, semantic, and generic features of the discourse practices under description.

That said, there is a small body of work that uses discourse analytical methods for understanding and enhancing clinical–organizational communication. Especially interesting for the purposes of the present article is work that uses linguistic and discourse analyses to study multidisciplinary team meetings, with the aim of understanding the interprofessional dynamics between doctors and nurses, and how these affect care planning (Engstrom, 1986). Related findings range from the extent to which professional habitus enables or constrains cross-professional communication (Lingard *et al.*, 2002), to how professional identities appear to determine the character of work meetings, resulting in highly variable impacts of executive-level decisions (Iedema *et al.*, 1999), to how clinicians structure their communications as complex 'polylogues' (Grosjean, 2004). Also working across clinical–professional boundaries, Mellinger reported an interactive analysis of how paramedics and nurses coordinate their practices in environments filled with high levels of urgency and uncertainty (Mellinger, 1994).

Focusing specifically on the logic and complexity of doctors' practices and their relationship with clinical

documentation, Pettinari (1988) wrote an extensive study about the ways in which surgeons work and how they make notations about their work, illuminating the degrees of tacit knowledge and presumed understanding that come into play there. For her part, Hobbs has also performed some important work on elucidating the medical assumptions underpinning the technical codes and symbols of clinical notation in residents' progress notes (Hobbs, 2002). Others have addressed the work–documentation relationship, but from a sociotechnical angle, including Timmermans and Berg (1997).

The complexities of various kinds of medical treatment are described in the work by Mol (2002) and Fox (1993), both of whom use versions of discourse-based ethnography. With regard to analyses of talk by doctors as professional identities, Montgomery-Hunter (1991) studied a variety of dimensions of medical discourse, such as case presentations and medical records as 'doctors' stories,' and Jordens and Little (2004) described how doctors frequently position themselves in interview talk by enunciating a genre that is agnate to the Directive.

Surprisingly, given the enormous changes that it has undergone in recent decades, there is limited work that has addressed the relationship between doctors and managers (Griffiths and Hughes, 2000) or, more broadly, between clinicians and nonclinicians (Smith and Preston, 1996). It is these domains of investigation in particular that have least been broached by linguistic and discourse approaches, with some exceptions. Iedema *et al.* (2004) have addressed the delicate interactions occurring between clinicians and managers in a health care organization that faced hospital reform, whereas Pope *et al.* (2004) have studied the discursive tensions among policy statements, managers' views, and clinicians' uptake of the shift toward 'elective treatment only' centers. These analyses in effect contribute to redesigning the substance of the 'conversations' that currently characterize and constitute the clinical–managerial interface and to restructuring the evaluation of health care delivery based on those emerging conversations (Degeling *et al.*, 2004).

Prominent for our purposes too is research arising from within nursing. The work of Crawford *et al.* (1998) analyzes nursing discourse and offers insight into a number of facets of nursing care, including into how clinical notation relates to what is spoken about among nursing clinicians and into the socially constructed nature of clinical knowledge, its documentation, and its implications for how care is organized. Crawford and colleagues' work belong to a vibrant tradition of nursing research that applies discourse analysis as methodology for illuminating general nursing issues (Boutain, 1999; Lawson, 2002).

A thorny issue for nursing research is how the nurse–doctor relationship impacts on what the nurse does. Manias, Street, and Cheek are among some nursing researchers doing critical discourse ethnographies of nurse–doctor interactions (Manias and Street, 2001) as well as of nurse–doctor communications enacted through chart notations and the like (Cheek and Gibson, 1996). Consonant with the concerns of these investigations, there is research emerging from within the discourse analytical tradition that also deals with doctors' and nurses' talk from the perspective of what it says about how they work together as members of multidisciplinary clinical teams (Iedema *et al.*, 1999).

Finally, innovative work on engendering new clinical practices involving different professionals as well as patients is emerging from the University of Helsinki under the guidance of Yrjö Engeström (see Engeström, 2003). Engeström's work is better categorized as belonging to what he terms 'Activity Theory' than to language or discourse research, and this is not least because he uses complex video data to describe and reflect on what clinicians do with and around patients. Examples of highly innovative practices designed in this way are reported in both Yrjö and Ritva Engeström's publications, centering on creating continuity of care across health caregivers and services by involving an acute-care specialist, a general practitioner, and the patient in his/her care planning meetings (Engeström, 2003). It is studies like these that are truly beginning to reinvent relationships and services in health care systems that for too long have relied on the image of the autonomous doctor epitomized by the doctor–patient consultation. Here, new conversations such as that presaged in Degeling *et al.*'s (2004) work cited above are beginning to be proactively configured and investigated, in a move toward recognizing that the organization of doctoring is no longer a peripheral issue to contemporary health care and medicine.

Conclusion

In closing, let us return to the theme we started with. Above, we cast a brief glance at the contents of the major linguistics and discourse analysis publications, including journals, overview publications, and collected papers. It was stated that emphases in these publications were placed on how doctors communicate with patients (and vice versa) and on how medical discourse has written itself in the past or writes itself in the present. The article proceeded to argue that the orientations of medical discourse research are

out of step with the face of 21st century medicine. Only a minority of researchers have taken steps not just to contextualize the study of medical and clinical discourses and practices with emerging consumer, managerial, policy, and organizational issues in health care, but to shift the focus of description from the medical consultation (which stopped being the apotheosis of health care with the shift toward medical and information technologies) toward the multidisciplinary team and focus on the ways in which it plans, communicates, and delivers care.

This article suggested that, if medicine operates in complex social, cultural, organizational, and political environments, few of which can be relied on to 'spring spontaneously from the discourse', linguistic and discourse researchers may need to rethink the basis of their methodology as well as the focus of their approach to medicine as a disciplinary regime. With regard to methodology, we reiterate Cicourel's (1982) call for a more ethnographically informed kind of linguistic–discourse analysis. As for linguistics' focus on the discourse of medicine, I have argued that the task of a socially and organizationally aware and practice-oriented analysis is to understand and clarify the dynamics of, and the struggles that choreograph, the contexts of which its objects of investigation are part. Put differently, analysis should not fall victim to the notion that the empirics of situated language production can substitute for an analysis of social life. Particularly at a time when health care is changing on an almost daily basis and is increasingly under pressure from more and more parties claiming interest and influence, our engagement, as linguists and discourse analysts, with processes through which the new medicine is increasingly being constituted is no longer a luxury option.

Finally, several publications that combine delicate linguistic analyses with penetrating commentaries on the changing nature of medicine and health care have been cited. On that score, the present article bears witness to the fact that meaningful social engagement and linguistic delicacy are far from a zero-sum game. On the contrary, the subtext driving this article is that linguistic and discursive analysis is central to not just understanding and clarifying health professional and organizational change for ourselves as analysts, but provides a means to enable professionals to come to terms with the increasingly challenging complexities of their clinical work.

English: Its Role as a Lingua Franca in the Techno-scientific Field of Medicine

A lingua franca is a common language serving as a regular means of communication relating to scientific, technological, and academic information between different linguistic groups in a multilingual speech community. Historically speaking, English first evolved as a lingua franca in the late 19th and early 20th centuries as a result of the British Empire, which exported its own language to all corners of the earth. In the second half of the 20th century, the American Empire replaced the British Empire throughout the world. English has reasserted itself as a medium for universal communication in an increasingly interconnected world.

English is now the dominant or official language in over 60 countries and is represented on every continent (Crystal, 1997). Moreover, English is the dominant voice in international politics, banking, the press, news agencies, broadcasting, the recording industry, motion pictures, travel, technology, knowledge management, and communications. It is the main language of the Internet, not to mention books, newspapers, airports and air traffic control, international business and academic conferences, sports, international competitions, pop music, and advertising. English has equally become the common language of international experts in a wide range of subjects, such as medicine, the natural sciences, and the social sciences. In addition to this, an estimated three-quarters of the world's mail is written in English and most of the information stored in electronic retrieval systems is in English. Consequently, English is now needed in order to adjust to the world trend of keeping pace with scientific, technological, economic, and social advances.

English as a Medium of International Communication in the Medical Sciences: Extralinguistic Factors

The rise of English as the lingua franca of science and technology in the second half of the 20th century seems to be determined by cultural and extralinguistic factors rather than by inherent linguistic characteristics. The origin of this phenomenon does not lie in any inherent stability of English for its adoption as an international language, but in the sociopolitical

In addition to this, an estimated three-quarters of the world's mail is written in English and most of the information stored in electronic retrieval systems is in English. Consequently, English is now needed in order to adjust to the world trend of keeping pace with scientific, technological, economic, and social advances.

English as a Medium of International Communication in the Medical Sciences: Extralinguistic Factors

The rise of English as the lingua franca of science and technology in the second half of the 20th century seems to be determined by cultural and extralinguistic factors rather than by inherent linguistic characteristics. The origin of this phenomenon does not lie in any inherent stability of English for its adoption as an international language, but in the sociopolitical

changes that, mainly due to the Anglo-American influence, have taken place after World War II. All the countries in Western Europe have been affected to a greater or lesser degree by this dominant role of the United States of America, which is related to several well-known factors, such as their military, political, economic, scientific, and technological leadership, as well as the creation of the Atlantic Alliance and the diffusion of the culture, lifestyles, and behaviors of the English-speaking world. English has equally become a prime vehicle for the transmission of information, which explains its nearly absolute dominance in most scientific fields, because not only the world's most widely cited medical journals but also most of the best contributions in science and medicine are published in English in international European or American journals. To this overall presence of English in traditional written communication systems, we must add the World Wide Web and the computer networking Internet, whose predominantly English voice has been rapidly exported from and imported into many languages. Therefore, non-English-speaking scientists, researchers, and practicing doctors have no other option but to learn English if they want to be informed of the latest developments in their fields.

As English has turned into the primary medium of international specialized publication, many non-English-speaking scientists, being aware of the relevance of medical literature in English to their work and wanting to obtain responses to it, find it more effective to publish in English than in their native language. In this respect, it is interesting to note that many nations measure the productivity of their top international scientists and scholars by the number of times their works are quoted in English-language publications with an impact factor by the Science Citation Index. The increasing tendency toward publishing the most important contributions in English and in top general-science journals, usually published in English, runs parallel to the standardization of research lines and the uniformity of writing style dictated by the editorial boards of scientific journals whose members, in a large proportion, have English as their mother tongue.

Apart from being the primary medium of scientific publication, English has likewise emerged as the main language of international gatherings of specialists and of international scientific exchanges. In fact, the high level of technical and scientific knowledge, the necessity of collaboration among several specialists in order to establish a common base for work, and the complexity of the organization of production and of services in today's society are all factors that foster the use of the same technical terms contemporaneously. This trend to increasingly use one lingua franca, and in relatively few journals for each science, favors a smoother communication between scientists and, consequently, a rapid progress in science.

The continually increasing contact between non-English-speaking scientists and the English-speaking scientific world, mainly through reading and, to a lesser extent, through writing and attending conferences, even reaches meetings of the national type and daily informal conversations between colleagues and national journals, where many English terms tend to creep in. The publishing scientists are equally given stylistic and rhetorical recommendations to write academic papers in their own native language, which follow and imitate the norms characteristic of the foreign English culture.

Despite the obvious advantages of the existence of English as a lingua franca, its achievement nevertheless runs parallel to a series of interrelated drawbacks. One of the disadvantages caused by the supremacy of English in the world of science would be that the body of medical knowledge published in other languages is not taken into account. This fact indicates ignorance of the role played by these languages in the different phases of creation, invention, and innovation, and this may lead to uniformity of thought. Also at issue is the scarce participation of non-English-speaking scientists in the editorial policies of the major internationally recognized journals.

Borrowing: Linguistic and Extralinguistic Factors

Borrowing is one of the normal neological processes that every language has at its disposal to enrich its lexis. This neological process consists of two consecutive operations. First, a speaker is put in contact with a foreign word and adopts it in his or her language. This does not mean that the adopted word is used as it is in the original language. Usually, the speaker adapts the foreign word to the phonetics of the language he or she speaks. Then comes the diffusion and establishment in the recipient language of the generally phonetically adapted loanword. Thus, the former transfer is essentially an individual act, which can be completed by the latter, diffusion and establishment, which involves collective acceptance, and results in integration.

Since all loans are neologisms, the underlying cause of borrowing, from either internal or external sources, is fundamentally the same as that of neologisms in general, i.e., the need for language, as a means of communication and expression, to take account of changes in the nonlinguistic world. But

loanwords differ from other types of neologisms in that their components or models are taken from external, and not from internal, sources. As far as the external source is concerned, drawing loanwords from any foreign language, which is traditionally known as "lexical borrowing" (Haugen, 1950; Hope, 1971), is a direct consequence of a response to the internal lexical needs of a recipient language. The extension of the frontiers of knowledge in science and technology in particular has been accompanied by the creation of a vast terminology necessary to describe the discoveries made and to express the concepts that evolved in the course of this development. As English has become the international language used in science and technology, it is not surprising that it has become the primary source for the creation of new concepts and their corresponding denominations. These new concepts tend to carry their names into the adopting languages, becoming on many occasions integral parts of their word stocks.

Every language (unless it is a dead language, such as Latin) cannot avoid interference with other countries and other cultures, especially when this language has become a lingua franca in several fields of knowledge. This is the case for English, which had been a receiving language for centuries and is now supplying other languages with the necessary English loans or Anglicisms. Sometimes the speed of development of new knowledge, which requires new words for new concepts, does not allow enough time to find a suitable translation, or it may be that laziness prevents this translation to be found. The tendency toward economy of expression and the law of least effort can also be responsible for borrowing because the borrowed element is frequently a short term that the speaker and, above all, the writer are inclined to adopt, or it is often quicker and easier to borrow the foreign terminology along with the science, behavior, or product than to mine one's own language for a suitable expression. Economy of expression is not the only purpose that prompts the use of English loanwords. Often the employment of a new and shorter term aims at precision and clarity if the recipient languages do not dispose of an unequivocal equivalent. The transfer of Anglicisms can also be accounted for by the scientists' extensive reading of English-written medical literature. Another common feature, such as the greater facility with which English produces noun compounds, equally favors the adoption of straight English loanwords. Although the borrowed terms can be rendered by means of glosses and paraphrases, the lack of specificity and economy of some of the proposed solutions may lead to the conservation of their original form. The avoidance of homonymic clash may likewise induce keeping the borrowed term unchanged, for instance, the English term *shock*, which has come into Spanish in order to avoid being identical in form and sound with the already existing Spanish word *choque*.

These linguistic factors are not solely responsible for the adoption of Anglicisms. Social and psychological pressures also enter strongly into the promotion or assurance of their acceptability. The new foreign loanwords, associated with the strongest nation in the world, i.e., the United States of America, quite naturally take on certain general attributes of prestige, as they may evoke an image of quality, efficiency, reliability, and modern living. Also important is the in-talk of certain professional groups, who may rely on a borrowed terminology to mark their status while excluding others. Usually quoted examples are the medical and legal professions. Sometimes the adoption of English loanwords is prompted by the desire for a euphemistic term to express in a less direct way concepts regarded as painful or embarrassing. Pretentiousness and snobbery can equally cause words containing grouping of letters impossible in non-English languages to have an attraction for their speakers, who may also be tempted to borrow terminologies wholesale from English either for international comprehensibility or for greater acceptance among their peers.

Medical Anglicisms: Their Presence in Non-English European Languages

Medical terminologies, at least in Western Europe, rest on a fundamentally Latin nomenclature and on neologisms built up with roots, prefixes, and suffixes drawn from Greek and Latin, especially in the fields of anatomy and physiology (Dirckx, 1983). From the Middle Ages to the recent past, Latin, German (Standard German), and French all served traditionally as international languages in the field of medicine. Traces from other European languages, such as Italian and Spanish, may be found as well. Non-European languages have contributed, although to a lesser degree, to the formation of international medical terminology. But on the whole, the current growth of this melting pot of words from different origins is mostly due to the clear supremacy of the United States of America, which, especially after World War II, has been very strong (Maher, 1986). As English has turned into the most powerful medium of medical and scientific communication in Europe, it is not surprising to find hundreds of English words whose use has become common and standard in other European languages. Even a large proportion of these English words are now commonly found in medical

dictionaries written in languages other than English, which is proof of their acceptance within non-English-speaking medical communities.

The influence exerted by medical English on other European medical languages has affected all levels of their linguistic systems, ranging from lexis and semantics to syntax and rhetorico-pragmatics, with the borrowing of vocabulary items being nevertheless by far the most common.

Lexico-semantic Level

A technical term is defined on the basis of a direct relationship with the thing signified. This is why, in the contact between two cultures and languages, technical terms generally pass from one to the other along with the things they denominate. The vast majority of the borrowed sequences reveal themselves as foreign because of their spelling pattern, which may contravene the rules of syllable structure or phonemic distribution of the recipient languages. Examples of univerbal lexical Anglicisms with geminated vowels and consonants, consonant clusters, unusual graphs, or graphs in unusual positions found in many non-English European medical terminologies would be, for instance, words such as those found in Table 1. Scores of multiverbal lexical Anglicisms with consonant groupings are listed in Table 2.

The form of a word sometimes encourages the preference for an unadapted Anglicism. Compounds that contain a noun and a particle are generally considered difficult to translate or impossible to translate adequately. This is why they can be found in various domains related to medicine (see Table 3).

The economy of expression given by the *-ing* form also makes it an extremely popular structure with specialist writers, and it is not strange to find it in a wide series of simple and compound terms, such as those found in Table 4.

Although the vast majority of graphically unassimilated Anglicisms do reveal themselves as foreign, because of either their orthographic pattern or the lack of relation between pronunciation and spelling, there are several borrowed terms the spelling of which fits perfectly into the morphological patterns of the adopting language. Among these we could include words that are seldom pointed out by inverted commas or italics (see Table 5).

In some cases, the borrowed words acquire native status by the degree of adaptation they undergo. This adaptation allows the foreign word to be adjusted to the prosodic, phonetic, or spelling norms of the borrowing language. Examples of words once considered to be foreign but fully adapted into a language such as Spanish would be the adjective *standard* and the noun *stress*, which have become *estándar* and *estrés*, respectively, in order to sustain the Spanish principle that a word should be written as it is pronounced.

The role as a donor language played by English is also especially noted in the field of abbreviations, which are simply adopted by the recipient languages. Particularly common in medical writing are the initialisms, which consist of the first letters of the words that compose a phrase and which are especially popular for the names of diseases and of diagnostic and therapeutic procedures. These initialisms are not only understood within the profession, but they are also almost invariably substituted, even in print, for the full expressions. For example, *corticotropin* is probably better known by the initialism ACTH (adrenocorticotropic hormone) than by its full native name. The same happens to other compressed forms (see Table 6).

Table 1 Lexico-semantic level

PUFA (polyunsaturated fatty acids)
SPET (single-photon emission tomography)

Table 8 Semantic level

Buena práctica clínica 'good clinical practice'
Célula asesina 'killer cell'
Célula huésped 'host cell'
Dosis umbral 'threshold dose'
Efecto techo 'ceiling effect'
Estudio doble ciego 'double-blind study'
Línea basal 'baseline'

Another type of abbreviated form is the "acronym," i.e., an initialism that can be, and customarily is, pronounced like a word. Very common English medical acronyms include those found in Table 7.

The bulk of loanwords borrowed from English usually belong to the nominal category, whereas the adjectival category plays a very small part. Exceptions in the language of medicine, and mainly used orally, would be adjectives such as *low*, *high*, or *light*, which, on the other hand, are not technical terms but words used in both common and specialized languages. A rare case of importation of adjectives in the written form would be the expressions *slow-low* and *rapid-high*.

Worth mentioning is the fact that when an English word is taken into a foreign language, an adaptation of its meaning usually takes place. This adaptation follows a general tendency to narrowing of meaning, a fact especially obvious with items that are polysemic in the source language, and it is therefore usual for them to be borrowed from one specific context and with one meaning. The same term, together with its specific meaning in each case, may also be borrowed from other contexts and may be found in different medical branches and even in other fields outside medicine. For instance, *scaling* belongs to dermatology, odontology, and statistics, whereas *loop* has entered not only medicine but also aeronautics, computer science, and economics.

Semantic Level

Another quite frequent means of expressing new concepts in a recipient language is through semantic borrowing, which consists of applying a foreign meaning to a native word and which sometimes cannot be easily identified because a native element is involved. Two main word-formational devices can be distinguished under this type of borrowing: (1) semantic loanword, for which a native word acquires a new meaning under the influence of the corresponding English cognate, i.e., a word derived from the same, generally Latin root; and (2) loan translation or *calque*, which is the result of the translation of an English collocation into the recipient language. It is significant that many examples of semantic loanwords, once numbered among the so-called *faux-amis* or *false friends*, i.e., words that are spelled the same, or almost the same, in two different languages but have different meanings, today have become current usage in medical literature. Good cases of semantic loanwords would be those of the Spanish verb *asumir*, which has taken on the additional English meaning of 'to assume,' or of the Spanish nouns *evidencia*, which is used as the equivalent of 'sign,' 'proof,' or 'testimony' under the influence of *evidence*, and *ocurrencia*, which, along with the meanings of 'idea' and 'funny remark,' is also used in the sense of 'happening,' according to *occurrence*. Examples of Spanish calques on English expressions are shown in Table 8.

Further examples of prepositional phrases in Spanish would be the eponymous expressions, which have always been widely diffused in the language of medicine. It is sufficient to mention just a few of these expressions composed of a proper noun and a common noun (see Table 9).

Syntactic Level

Although the impact on grammatical structure is less than that suffered by lexical and semantic levels, certain syntactic Anglicisms have definitively taken root. In Spanish, one of these Anglicisms would be an increased use of the passive voice instead of the more usual reflexive. The use of the gerund with a sense of posterity and consequence or effect would

Table 9 Semantic level

Ciclo de Ross 'Ross cycle'
Enfermedad de Parkinson 'Parkinson's disease'
Ley de Allen 'Allen's law'
Prueba de Addis 'Addis test'
Reacción de Porter 'Porter's reaction'
Signo de Hoover 'Hoover's sign'
Syndrome de Cushing 'Cushing's syndrome'

Table 10 Syntactic level

Campaña anti-aborto 'anti-abortion campaign' instead of *campaña antiabortista*
Carcinoma célula pequeña 'small-cell carcinoma' instead of *carcinoma microcítico* or *carcinoma de células pequeñas*
Depresión posparto 'postpartum depression' instead of *depresión puerperal* or *depresión del posparto*
Diabetes insulina-dependiente 'insulin-dependent diabetes' instead of *diabetes dependiente de la insulina*
Estudio caso-control 'case-control study' instead of *estudio de casos y controles*
Linfoma no-Hodgkin 'non-Hodgkin's lymphoma' instead of *linfoma no hodgkiniano*
Variabilidad interanálisis 'interassay variability' instead of *variabilidad interanalítica*

be another example of syntactic Anglicism. English equally appears to have encouraged the attributive use of nouns where Spanish requires adjectives or prepositions (see Table 10).

The greater flexibility of the adverbial position in English would have also led to the placement in new positions of adverbs and adverbials in other European languages. Moreover, there seems to be an increasing tendency in the written scientific Spanish language for the word order subject–verb–object, which might be owed to the influence of English, in which this word order is virtually fixed.

It is equally interesting to note the frequent appearance of the particle *like*, which can be combined in all sorts of compounds (see Table 11). All these compounds show the influence of English at the lexical and syntactic levels. On the one hand, the adopting lexicon is enriched with one English word, and, on the other hand, the preposition is placed after the noun and not before it, as is required by syntaxes such as the Spanish one. *Like* may also be added to words of the recipient language, thereby illustrating the linguistic phenomenon called 'loan blend,' i.e., formations between loanwords and calques (see Table 12).

Likewise, the mixture of calques and lexical Anglicisms should be noted in the Spanish expressions *célula helper* 'helper cell' and *célula natural killer* 'natural killer cell,' to mention just two of the many mixed syntagms that are characteristic of specialized

Table 11 Syntactic level

Myelin-like	*Inhibin-like*	*Heparin-like*	*Insulin-like*	*ICS-like*
HLTV-III-like	*PDGF-like*	*PUU-like*	*5-HTL-like*	

Table 12 Syntactic level

Anfetamina-like 'amphetamine-like'
Colágeno-like 'collagen-like'
Eczemática-like 'eczema-like'

languages where a feeling of urgency drives scientists to coin expressions with words from different origins. Other mixed words due to English influence would be the Spanish verbs *deletear*, *mapear*, *printear*, *reportar*, and *testar*, which conserve the first component of the English verbs 'to delete,' 'to map,' 'to print,' 'to report,' and 'to test,' respectively, and add them the verbal Spanish morpheme *-(e)ar*.

Phonemic Level

Language contact situations do not bring about phonemic importation as the original English phonemes are replaced in all cases by native phonemes, which are approximately equivalent and follow the native rules governing syllable-structure and stress. For instance, *stripper* /'strīpə/, whose initial 's' plus consonant does not exist in Spanish, is pronounced /es'triper/, even when the original spelling does not undergo any change. Another word with the unmodified spelling is *screening* /'skri:nīŋ/, which is pronounced /es'krinin/. Although there is no phonemic importation, the phonemic system does undergo change in that phonemic redistribution may take place as a result of the Anglicism, as occurs with plosive consonants, which may occupy new distributional paradigms, especially in the final position.

Typographic Level

An example of typographic Anglicism would be the attachment to a noun by means of a hyphen of prefixes, such as the neoclassical *anti-* and the temporal or sequential *pre-* and *post-* (see Table 13).

The use of English inverted commas, instead of the Latin ones, or the absence of graphic accents and wrong spellings would exemplify further cases of typographic Anglicisms in Spanish (see Table 14).

Rhetorico-pragmatic Level

The extensive reading of English-written sources and of style manuals for writing academic papers, which are mostly translations of English papers, have led scientists worldwide to imitate some of the preferred English attenuating rhetorical patterns (Salager-Meyer

Table 13 Typographic level

Anti-alérgico 'anti-allergic'
Anti-núcleo 'anti-core'
Pre-núcleo 'pre-core'
Pre-test 'pre-test'
Post-test 'post-test'

Table 14 Typographic level

Catatonia 'catatonia' instead of *catatonía*
Osteitis 'osteitis' instead of *osteítis*
Colorectal 'colorectal' instead of *colorrectal*
Halucinación 'hallucination' instead of *alucinación*
Linfokina 'lymphokine' instead of *linfocina*
Hematopoiesis 'hematopoiesis' instead of *hematopoyesis*
Amfotericina 'amphotericine' instead of *anfotericina*

et al., 2003). The usual English tendency toward hedginess may be seen in Spanish in the epistemic use of modal auxiliary verbs expressing possibility, such as *puede(n)* 'can/may,' *podrían(n)* 'could/might,' in a greater use of the semi-auxiliary verb *parece(n)* 'to appear/to seem,' or in the presence of adjectives, adverbs, and nouns related to the modals (see Table 15).

The influence of English-speaking thought patterns may be equally responsible for another rhetorical strategy used abundantly today, i.e., the responsibility shifting that allows the researchers to 'defocus' the agents (researchers and readers) involved in the communication act and to focus on the information being transmitted.

The exclusive use of a correct term in the adopting languages to the detriment of possible synonyms might equally be owed to English influence. This would be the case of the Spanish verb *sugerir,* which, due to the influx of its English cognate *suggest*, has a greater frequency of occurrence than some of its synonyms, which could express in a better form the conclusion of a scientific work (see Table 16).

Table 15 Rhetorico-pragmatic level

Probabilidad 'probability'
Probable 'probable'
Probablemente 'probably'
Posibilidad 'possibility'
Posible 'possible'
Posiblemente 'possibly'
Quizás/quizá 'perhaps/maybe'

Indicar	*Inferir*	*Insinuar*	*Mostrar*
Permitir suponer	*Poner de manifiesto*	*Poner de relieve*	*Probar*
Proponer	*Recomendar*		

Pseudo-Anglicisms

Although borrowing in a strict sense consists of the transfer into a recipient language of a word together with one of its meanings, it may be that some words acquire semantic extensions beyond their original meanings when taken in by other languages. Examples of pseudo-Anglicisms found in Spanish would be the English verb *relax*, which has turned into a noun with the senses of 'break' and 'relaxation,' and the English noun *scanner*, referring to medical computed-tomography scanning, which in its already hispanicized form *escáner* has expanded to encompass not only the meaning of *escanografía* 'scanography' but also other nonmedical applications such as the scanners used in supermarkets to read barcodes. Other pseudo-Anglicisms that must count as fully native in Spanish would be *blister* or *gating*, which have never been used in British English or American English, to refer to *blister pack* and *cardiac gating*, respectively.

A Word in Closing

Political and military might, economic power, and techno-scientific superiority seem to be the main factors that have brought about the role of English as a lingua franca. In addition, its overall presence in the content posted on the Internet and its nearly absolute dominance in scientific publications have turned English as a prime vehicle for the transmission of information. The vastly greater amount of research in English-speaking countries has equally led many European and Asian languages to be somewhat behind the times with respect to the plethora of English terminology being created every day. This is why much of this terminology has found a degree of acceptance in these recipient languages.

Although the development of English as a world language may be seen with concern because it gives the originating cultures, namely, the British Isles and the United States of America, a certain advantage, especially in the world of science, medical loanwords may nevertheless be contemplated as a reflection of the standing progress of medicine, which needs an appropriate increase in its vocabulary to provide a fluid scientific communication, not to mention the fact that many of the borrowed Anglicisms are

eventually translated into the adopting languages or assimilated to their genuine linguistic rules.

Meeussen, Achille Emile (1912–1978)

P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born on April 6, 1912 in Sint-Pieters-Jette, Achille Emile Meeussen studied classical philology in Leuven. He obtained his Ph.D. in 1938 with a thesis in the field of Indo-European comparative grammar (more specifically, on the criterion for ablaut phenomena). In the 1940s, he started publishing extensively on Flemish (Vlaams) dialects, Dutch, and also on African languages, a field which he then had recently discovered for himself.

In 1950, Meeussen, after spending some time at the School of Oriental and African Studies in London, became staff member of the Musée royal du Congo belge (later: Musée royal de l'Afrique centrale) in Tervuren, and in 1952 he was also appointed professor in the African Institute at the University of Leuven, where he was able to form a generation of well-trained Africanists and descriptive linguists. When the African Institute was closed, Meeussen continued his teaching at the University of Leiden (1964–77); he also taught sporadically in Lyon. He remained attached to the linguistic section of the Tervuren museum until his death on February 5, 1978.

Meeussen did fieldwork on a wide variety of Bantu languages, and initiated a comprehensive project on the comparative grammar and the reconstruction of Bantu (at present the project is continued by staff members of the Tervuren museum). He also studied African literature, music, folklore, and customs. In addition, Meeussen wrote insightful papers dealing with problems of phonology, morpho(pho)nology, and syntax, concerning Dutch (his native language), Japanese, and a number of Algonquian languages (Unami or Delaware, Cheyenne, Blackfoot, Mistassini or Inland Eastern Cree; cf. Swiggers, 1983). His most important achievements, however, are in the field of Bantu linguistics: a very impressive synchronic realization is his grammar of the Rundi language (1959); and his most important comparatist publications are his Bantu grammatical (1967) and posthumously republished lexical reconstructions (1980).

Meeussen's approach was a structuralist one, and his work represents a very coherent, systematic, and highly authentic brand of structuralism, characterized

eventually translated into the adopting languages or assimilated to their genuine linguistic rules.

Meeussen, Achille Emile (1912–1978)

P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born on April 6, 1912 in Sint-Pieters-Jette, Achille Emile Meeussen studied classical philology in Leuven. He obtained his Ph.D. in 1938 with a thesis in the field of Indo-European comparative grammar (more specifically, on the criterion for ablaut phenomena). In the 1940s, he started publishing extensively on Flemish (Vlaams) dialects, Dutch, and also on African languages, a field which he then had recently discovered for himself.

In 1950, Meeussen, after spending some time at the School of Oriental and African Studies in London, became staff member of the Musée royal du Congo belge (later: Musée royal de l'Afrique centrale) in Tervuren, and in 1952 he was also appointed professor in the African Institute at the University of Leuven, where he was able to form a generation of well-trained Africanists and descriptive linguists. When the African Institute was closed, Meeussen continued his teaching at the University of Leiden (1964–77); he also taught sporadically in Lyon. He remained attached to the linguistic section of the Tervuren museum until his death on February 5, 1978.

Meeussen did fieldwork on a wide variety of Bantu languages, and initiated a comprehensive project on the comparative grammar and the reconstruction of Bantu (at present the project is continued by staff members of the Tervuren museum). He also studied African literature, music, folklore, and customs. In addition, Meeussen wrote insightful papers dealing with problems of phonology, morpho(pho)nology, and syntax, concerning Dutch (his native language), Japanese, and a number of Algonquian languages (Unami or Delaware, Cheyenne, Blackfoot, Mistassini or Inland Eastern Cree; cf. Swiggers, 1983). His most important achievements, however, are in the field of Bantu linguistics: a very impressive synchronic realization is his grammar of the Rundi language (1959); and his most important comparatist publications are his Bantu grammatical (1967) and posthumously republished lexical reconstructions (1980).

Meeussen's approach was a structuralist one, and his work represents a very coherent, systematic, and highly authentic brand of structuralism, characterized

by methodological consciousness, and an acute sense of rigor and descriptive economy. He developed a formally based approach to Bantu tonological structures and morphosyntactic structures, anticipating aspects of autosegmental phonology (Meeussen's name is attached to a rule by which a sequence of two high tones is changed into a sequence of high + low, or by which two accents are reduced to a single accent). In later years, Meeussen used the formalist framework of generative linguistics (especially generative phonology), without subscribing to its psycholinguistic and metatheoretical claims.

Meigret, Louis (?1500–1558)

D A Kibbee, University of Illinois, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Louis Meigret is best known today for his *Tretté de la grammère françoeze* (1550) and his work on orthographic reform (from 1531 to his death). He was born into an important family of jurists in Lyon and pursued the typical Humanist career of translator. He translated primarily from Latin, but also from Greek and Italian, focusing on works about the art of war and the natural sciences.

Meigret's first foray into linguistic analysis came in his formulation of a new orthography for the French language. Many complained of the lack of correlation between the spoken language and the written; Meigret supplied some concrete suggestions in 1531, although these were not published until 1542.

For Meigret, the battle for an orthography in which each letter stood for one sound, and each sound was represented by only one letter was part of the greater Humanist program, in which reason rather than superstition would reign. Ironically for this dedicated scholar of Greek and Latin, reason meant abandoning real or imagined connections between the spelling of the ancient languages and the spelling of French.

The battle cry for orthographic reform appeared in *Champfleury* (1529) by the printer Geofroy Tory. In the same year Tory mentioned his intention to publish 'General Rules for the Spelling of the French Language,' but this work never appeared. An anonymous treatise on French orthography was published later in 1529, with the goal of bringing French writing back to its former 'integrity.' While the author of that treatise and Jacques Dubois thought that re-establishing the integrity of French meant reverting to Latinate forms and morphological distinctions, Meigret took a radically different tack. Meigret's orthographic reform promoted spelling based on pronunciation, rather than on derivation and etymology. He was immediately attacked by Guillaume des Autels, with whom he had an extended public debate, and then by Jacques Peletier du Mans and Théodore de Bèze. The publication in 1548 of his translation of Lucian of Samosata's *Philopseudes* (*Le menteur*) in his reformed orthography, as well as his own *Tretté de la Grammère Françoeze* in 1550, demonstrated the scientific interest and the practical failure of his reform. Readers found his system virtually impossible to decipher.

In spite of the difficulties presented by its writing system, the *Tretté de la Grammère Françoeze* is arguably the most original and most interesting work on the French language in the 16th century. It is divided into 11 books, some quite short. The first deals with the sounds of French, and the articles. The next seven are devoted to the parts of speech (noun, pronoun, verb and participle, adverb, preposition, conjunction, interjection), the last three to prosody and punctuation. Throughout, Meigret grapples with the question

by methodological consciousness, and an acute sense of rigor and descriptive economy. He developed a formally based approach to Bantu tonological structures and morphosyntactic structures, anticipating aspects of autosegmental phonology (Meeussen's name is attached to a rule by which a sequence of two high tones is changed into a sequence of high + low, or by which two accents are reduced to a single accent). Meillet, Antoine (Paul Jules) (1866–1936)

T C Christy, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

Antoine Meillet, whose teachers included Ferdinand de Saussure, Louis Havet, Victor Henry, James Darmesteter, and Michel Bréal (whom he succeeded at the Collège de France), is widely known for his contributions to the fields of comparative Indo-European linguistics, classical studies, the Slavic languages, Armenian, and general linguistics. Among his many publications, those included in the Bibliography below have gone through numerous editions and translations and stand out in terms of both their contemporaneous impact and their enduring relevance. Of perhaps greatest importance in terms of contemporary relevance is the collection of his major linguistics articles published under the title *Linguistique historique et linguistique générale* (1958; originally published as vol. 1, 1921, vol. 2, 1936). Two articles in this collection merit special attention. In his '*Comment les mots changent de sens*' (1906, 1958: 230–271) Meillet considers language to be first and foremost a social fact, and accordingly seeks social causes for semantic change. In '*L'évolution des formes grammaticales*' (1912, 1958: 130–148) Meillet coins the term "grammaticalization" (1958: 133) to describe the process whereby words, through combination and habituation, lose their principal meaning to become accessories, grammatical markers. Grammaticalization is now a central topic in linguistic research (cf., e.g., Hopper and Traugott, 1993; Ramat and Hopper, 1998).

See also: Armenian; Bréal, Michel Jules Alfred (1832–1915); Cultural and Social Dimension of Spoken Discourse; Evolution of Semantics; Evolution of Syntax; Grammaticalization; Morphologization; Saussure, Ferdinand (-Mongin) de (1857–1913).

Meinhof, Carl Friedrich Michael (1857–1944)

S Pugach, Ohio State University, Lima, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Along with Diedrich Westermann, Carl Meinhof is usually considered one of the main founders of the discipline of African linguistics – Afrikanistik – in Germany (*see* **Westermann, Diedrich Hermann (1875–1956)**). He was born on July 23, 1857, in Barzwitz, a village in the Pomeranian county of Schlawe that is now part of Poland, and died of old age on February 11, 1944, in Hamburg. He was descended from a long line of Swabian pastors, who included his father, Friedrich. His mother, Clara Giesebrecht, came from a noted intellectual family: Meinhof's grandfather, Karl Ludwig, was a poet and director of the Grauen Kloster high school in Berlin; his great-uncle Ludwig was a prominent 19th-century poet and philosopher; and his uncle Wilhelm was an historian of the Holy Roman Empire.

Meinhof was to follow both his father's and mother's families, becoming a minister and a scholar. He had 11 siblings, two of whom were among his first teachers as he began his education at home in Barzwitz. In 1868 Meinhof moved in with a relative in Halle, where he first attended Gymnasium, and in 1875 progressed to the University of Halle. Meinhof's concentration was theology, and he worked under Luther expert Julius Köstlin. After transferring to the University of Erlangen, Meinhof started to study Germanistik and to conduct linguistic research. He worked briefly but intensely with philologist Rudolf von Raumer (*see* **Raumer, Rudolf von (1815–1876)**), an author who wrote on the theories of August Schleicher (*see* **Schleicher, August (1821–1868)**) and was concerned with such issues as standard orthography, phonetic change, and language origins. Raumer was interested in demonstrating a genetic connection between Indo-European and Semitic languages (Raumer, 1863, 1876), and his theories had an undeniable impact on Meinhof, who in his later career focused on proving relationships among the Semitic, Hamitic, Bantu (Bantoid), and Nigritic language families in Africa.

Meinhof returned to religious studies in 1877, transferring yet again to the University of Greifswald, where he passed a series of theological exams in 1878 and 1879. After sitting for his examinations, Meinhof worked briefly as a high school teacher in Wolgast and Stettin, and in 1886 took a post as pastor in the small Pomeranian town of Zizow, not far from his family home in Barzwitz. All the while he continued his studies, passing more examinations, learning Assyrian, Aramaic, and Arabic, and expanding an already solid background in Hebrew. In Zizow, Meinhof also discovered his passion for Africa and chose to abandon the study of Asian languages for African ones in order to serve Germany's colonial interests (Pugach, 2001). He studied Duala and related Cameroonian languages with a Cameroonian named Njo Dibone, and began to teach these and other African languages to missionaries. He wrote several articles on Duala and related dialects that appeared in the *Zeitschrift für Afrikanische Sprachen*, and in 1899 published the *Grundriss einer Lautlehre der Bantusprachen* (*An introduction to Bantu phonology*), which soon became a standard in the field of African linguistics. The *Grundriss* offered phonological descriptions of six Bantu languages, including Swahili and Duala. The book also described an Urbantu, which Meinhof distilled from knowledge of the vocabulary, morphology, and grammar of the contemporary Bantu languages (Meinhof, 1899, 1910, 1932). The concept of Urbantu was similar to that of 'Urindogermanisch,' a term that August Schleicher had proposed to describe the parent of the Indo-European or Indo-Germanic language family (Schleicher, 1866). Meinhof also went beyond Urbantu in the *Grundriss*, providing a description of Bantu noun classes that was considered the most complete in existence until the publication of Malcolm Guthrie's work in the 1970s (*see* **Guthrie, Malcolm (1903–1872)**).

After the publication of the *Grundriss*, Meinhof was hired to teach African languages at the Seminar für Orientalische Sprachen in Berlin. He continued his research on Bantu there and at the Hamburg

Sebeok, Thomas A (ed.) (1966). *Portraits of linguists: a biographical* (Source book for the history of western linguistics 1746–1963, 2 vols). Bloomington: Indiana University Press.

After transferring to the University of Erlangen, Meinhof started to study Germanistik and to conduct linguistic research. He worked briefly but intensely with philologist Rudolf von Raumer (*see* **Raumer, Rudolf von (1815–1876)**), an author who wrote on the theories of August Schleicher (*see* **Schleicher, August (1821–1868)**) and was concerned with such issues as standard orthography, phonetic change, and language origins. Raumer was interested in demonstrating a genetic connection between Indo-European and Semitic languages (Raumer, 1863, 1876), and his theories had an undeniable impact on Meinhof, who in his later career focused on proving relationships among the Semitic, Hamitic, Bantu (Bantoid), and Nigritic language families in Africa.

Meinhof returned to religious studies in 1877, transferring yet again to the University of Greifswald, where he passed a series of theological exams in 1878 and 1879. After sitting for his examinations, Meinhof worked briefly as a high school teacher in Wolgast and Stettin, and in 1886 took a post as pastor in the small Pomeranian town of Zizow, not far from his family home in Barzwitz. All the while he continued his studies, passing more examinations, learning Assyrian, Aramaic, and Arabic, and expanding an already solid background in Hebrew. In Zizow, Meinhof also discovered his passion for Africa and chose to abandon the study of Asian languages for African ones in order to serve Germany's colonial interests (Pugach, 2001). He studied Duala and related Cameroonian languages with a Cameroonian named Njo Dibone, and began to teach these and other African languages to missionaries. He wrote several articles on Duala and related dialects that appeared in the *Zeitschrift für Afrikanische Sprachen*, and in 1899 published the *Grundriss einer Lautlehre der Bantusprachen* (*An introduction to Bantu phonology*), which soon became a standard in the field of African linguistics. The *Grundriss* offered phonological descriptions of six Bantu languages, including Swahili and Duala. The book also described an Urbantu, which Meinhof distilled from knowledge of the vocabulary, morphology, and grammar of the contemporary Bantu languages (Meinhof, 1899, 1910, 1932). The concept of Urbantu was similar to that of 'Urindogermanisch,' a term that August Schleicher had proposed to describe the parent of the Indo-European or Indo-Germanic language family (Schleicher, 1866). Meinhof also went beyond Urbantu in the *Grundriss*, providing a description of Bantu noun classes that was considered the most complete in existence until the publication of Malcolm Guthrie's work in the 1970s (*see* **Guthrie, Malcolm (1903–1872)**).

After the publication of the *Grundriss*, Meinhof was hired to teach African languages at the Seminar für Orientalische Sprachen in Berlin. He continued his research on Bantu there and at the Hamburg

Kolonialinstitut, where he transferred in 1909. Meinhof also started to research African languages that were not Bantu, and published an article on west African Fulbe (Adamawa Fulfulde) that posited the language as a bridge between Africa's Hamitic and Nigritic languages (Meinhof, 1911). This was controversial, because Meinhof's understanding of the differences between the Hamitic and Nigritic language families was part linguistic and part racial, a fact that was not lost on linguists of the time (Schuchhardt, 1912; Sapir, 1913). Those groups that spoke Hamitic languages – a categorical designation that linguists have since dismissed – were commonly classified as racially 'superior' to the Nigritic speakers, who were said to have darker skin than the Hamites (Saunders, 1969). Nonetheless, Meinhof insisted that his work was purely linguistic and continued to publish on the Hamitic languages for much of his career, most notably in the *Sprachen der Hamiten* (*Languages of the Hamites*) (Meinhof, 1912). However, because of his racialized discussion of African languages, Meinhof's relevance waned after his death, when Joseph Greenberg demonstrated that many of his theories were false and relied more on pseudoscientific biological evidence than linguistic proof (Greenberg, 1966).

Meinong, Alexius (1853–1920)

E Shay, University of Colorado, Boulder, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Alexius Meinong (Alexius von Meinong, Ritter von Handschuchsheim) was born July 17, 1853, in Lemberg, Austria (now L'viv, Ukraine), to a family of minor German nobility. He attended the Vienna Academic Gymnasium and enrolled in 1870 at the University of Vienna. After receiving a degree in history in 1874, he turned to the study of philosophy under positivist philosopher Franz Brentano. Meinong's first academic appointment, as *Privatdozent* (lecturer), was at the University of Vienna in 1878. In 1882 he accepted an associate professorship in philosophy at the University of Graz. He was promoted in 1889 to full professor, the position he held until his death on November 27, 1920. In 1894 he established Austria's first laboratory for experimental psychology at Graz.

Like Brentano, Meinong viewed philosophy not as a potential answer to metaphysical questions but as an empirical science. He proposed that if relationships among cognition, perception, language and reality could be clarified, then topics such as morality and ethics and emotions could be discussed in empirical terms, ultimately resulting in a synthesis of philosophical thought. To this end, Meinong developed a theory of assumptions, a theory of evidence, a theory of value, and a theory of objects (*Gegenstandstheorie*).

The first theory has to do with the nature of assumptions and the role they play in social phenomena, including communication. The theory of evidence concerns types of evidence used in reasoning and communicating: direct vs. indirect evidence, *a priori* vs. *a posteriori* evidence, and evidence for certainty vs. evidence for presumption. The theory of value involves emotional reactions associated with the existence of certain objects. The theory of objects concerns the ability to think about and describe objects that do not exist, e.g., round squares, and its ramifications for the notion of meaning: "What a speaker wants to 'say,' or, more exactly, what he wants to speak about, is not that which his words *express*, but that which they mean, and that is not the content, but the object of the idea expressed by the word" (Meinong 1899; translated in Lindenfeld 1980, 135–136).

Meinong's work, which lies at the intersection of philosophy, psychology and linguistics, was cited in contemporary and later works by Frege, Saussure and Russell. His discussion of relationships among thought, symbol and meaning have application in the fields of cognitive linguistics and formal semantics.

Mel'čuk, Igor Aleksandrovic (b. 1932)

J Léon, Université Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Igor A. Mel'čuk is well known for his Meaning-Text Theory, which nowadays is developing into a leading model in computational linguistics. He has also made significant contributions to morphology with the five volumes of his *Cours de Morphologie Générale* (1993–2000), and to computational lexicology with the four volumes of his *Dictionnaire explicatif et combinatoire du français contemporain. Recherches lexico-sémantiques* (1984–1999). It is notable that his main theoretical insights were already present in his early works as a pioneer of early machine translation in the Soviet Union in the 1950s, and of the design of a semantic intermediary language method for machine translation.

Mel'čuk was born in 1932 in Odessa, which was then part of the Soviet Union. He was trained in Spanish and graduated in French in 1956 at the Faculty of Philology at Moscow University. At the instigation of mathematician A. A. Ljapunov (1911–1973), who directed the Steklov Mathematical Institute of the Russian Academy of Sciences in Moscow (MIAN), he worked on an algorithm translation from French into Russian with Ol'ga Kulagina. At that time, he was participating in the seminars on machine translation organized by Viktor Jul'evic Rozencveig (1911–1998), where he met Aleksandr K. Žolkovskij (b. 1937) and Juri D. Apres'jan (b. 1930). He began a Ph.D. on Tocharian languages supervised by the comparatist Vjaceslav V. Ivanov (b. 1929), but in 1957 Ivanov and Mel'čuk were dismissed from their post at the university after having supported the Nobel Prize writer Boris L. Pasternak (1890–1960). He then got a position at the Institute of Linguistics of the Academy of Sciences in Moscow until his emigration from the U.S.S.R. in 1977. In August 1975, he wrote a letter to *The New York Times* supporting physicist Andrej Sakharov and biophysicist Sergej Kovalev, and helped the dissidents Jurij Orlov and Anatolij Scaranskij. He was thus fired from the Institute of Linguistics, became a 'social parasite,' and eventually succeeded in leaving the U.S.S.R. in May 1977. Since September 1977, he has been a lecturer at the Linguistics and Translation Department of the University of Montreal.

It was during this early period that Mel'čuk laid the foundations of his main theoretical and practical achievements: semantic synthesis and the meaning text theory with Žolkovskij, lexicography and semantics with the first drafts of the *Explanatory combinatory dictionary* with Apresjan and Žolkovskij, *Dependency syntax* with Nikolaj V. Pertsov (b. 1944), and finally his morphological work stemming from his treatment of grammatical meanings in machine translation.

As a pioneer in machine translation, the originality of Mel'čuk's work lay in his concern with synthesis and the transfer of meaning from one language to another, while most American researchers were focused on morphological and syntactical analysis. In the context of the strong Russian tradition of multilinguilism, he took the specific properties of languages into account and the constraints they impose on translation. Thus, Mel'čuk (1958) noted that word order, which was considered identical for every language, was different in Hungarian; this led him to plan an intermediary language for machine translation. This project was a semantic representation language, closely connected to Ivanov's protolanguage (Mel'čuk, 1960). It was based on a conception of languages as global systems – not separable into levels – for which a semantic theory must account. In the process of translation, grammatical meanings – a notion borrowed from Boas via Jakobson (1959) – are not identical from one language to another. Most morphosyntactical features, which are specific to each language and useful in the process of analysis, are no longer needed in the translation stage. On the contrary, what are needed are grammatical indicators of lexical meanings, used for lexical reference (i.e., tenses and modes of verbs). Therefore, the intermediary language is not designed as a grammar, but comprises both syntactic connections to stock syntactic meanings, and words in a dictionary to stock lexical meanings. Thus the intermediary language constituted a real semantic formalism resting on lexical functions and dependence grammar, which forshadowed Mel'čuk's meaning-text model. Besides, it led to the project of registrating the grammar of natural languages in dictionaries to carry out natural language generation (Mel'čuk *et al.*, 1984–1999). Mel'čuk's interest for morphology dates back from this early research too (Mel'čuk, 1993–2000). The Meaning-Text Theory was proposed by Mel'čuk and Žolkovskij (1967, 1970) as a framework for describing natural language as a multilevel correspondence between meaning and text, organized from meaning to text – that is, towards synthesis – to model the speaker's comprehension. Between meaning (the semantic level) and text (the phonetic level), there are two more levels, morphological and syntactic. Syntactic relations are represented by dependency trees (Tesnière, 1959) where nodes are

lexemes. In other words, there is no need for phrase-structure categories as syntactic information is located in the lexicon.

Currently the Meaning-Text Theory is gaining importance in several areas of formal linguistics and computational linguistics. It has been taken over by other formalisms, such as generative lexicon; since 2003, international conferences have been specifically dedicated to the developments in Meaning-Text Theory.

Memes

G Powell, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

In his 1976 book *The selfish gene*, the British zoologist Richard Dawkins proposed a new view on the nature of evolution. His overall claim was that evolution is driven not by species, nor by individual organisms, but rather by a more basic unit, the replicator, where a replicator is "anything in the universe of which copies are made" (Dawkins, 1982). His idea is that the engine of evolution is competition between distinct replicators, with a replicator's success determined, roughly speaking, by the number of copies it gives rise to. The most obvious of Dawkins's evolutionary replicators is the gene, the basic unit of biological evolution. But one of the insights offered by Dawkins's view was that evolution, viewed as an ongoing competition between self-propagating replicators, is not restricted to biology. For humans at least (and maybe in very limited respects for some other species), culture is also evolutionary: culture, just like biology, is a matter of the competition between particular replicators. But what are these cultural replicators? What is the cultural equivalent of the gene? Dawkins labeled it the 'meme.'

What Is a Meme?

Given the parallel with biological evolution, memes are defined as the basic units of cultural evolution. But what might they look like? They are essentially pieces of information, of whatever sort, which pass

Melanchthon, Philipp (1497–1560)

R Pozzo, Cattedra di Storia della Filosofia, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

A leading humanist scholar and a reformer at the side of Martin Luther, Melanchthon drew up the Confession of Augsburg and was the author of textbooks for all disciplines known in his time, from theology to physics. For reforming the curricula of university and higher education, he was acclaimed the Praeceptor Germaniae.

Born at Bretten on February 16, 1497, Melanchthon studied under his uncle Johannes Reuchlin until 1509; at the University of Heidelberg until 1512; and at the University of Tübingen until 1514. In 1518, he was appointed professor of Greek at the University of Wittenberg, where he taught for 42 years, until his death on April 19, 1560.

As regards the language sciences, Melanchthon was recognized by Desiderius Erasmus as early as 1518 for his Greek grammar, which was followed by a Latin grammar (Melanchthon, 1834–1860, vol. 20, pp. 3–179, 193–336). In his dialectic (Melanchthon, 1834–1860, vol. 13, pp. 507–702), he combined into a new methodical unity Cicero's doxastic Topic, the Stoic notion of systema, and the Aristotelian theory of demonstration. The relation between humanist and traditional logic during the Renaissance is a central issue with respect to the impact of Melanchthon's logic. Like many humanist logicians of his time, Melanchthon took a disruptive and destructive stance against traditional treatments of logic, achieving the result of discarding the more technical aspects of medieval logic while shifting the center of attention to nondeductive inferences, good arguments (in the sense of arguments that can be counted on to win in debate), and the problematic nature of arguments' validity (Jardine, 1988). In his rhetoric (Melanchthon, 1834–1860, vol. 13, pp. 27–506), Melanchthon developed two complementary oppositions: on the one hand, that between a persuasive, eloquent mode of expression as against an arid, uninspired, and technical machinery; on the other hand, an adequate, rhetorical analysis of a text, treating it as a coherent whole as against the medieval approach, which chops a text into inarticulate little pieces, tearing it apart in order to proceed to a formal interpretation of the fourfold significance of an argument (Meerhoff, 1994).

"Prudent men have discovered through experience that nothing is more difficult than to speak clearly and distinctly about a given subject" (Melanchthon, 2000): Melanchthon's concept of an integration of philosophical grammar, dialectic, and rhetoric was in fact revolutionary, insofar as the invention becomes consciously subordinated to the philosophical claims of searching for truth (Schanze, 1983).

Melanesia is a region of the Southwest Pacific which stretches from Irian Jaya in the west through Papua New Guinea, the Solomon Islands, Vanuatu, and New Caledonia, as far east as Fiji. © 2006 Elsevier Ltd. All rights reserved.

A leading humanist scholar and a reformer at the side of Martin Luther, Melanchthon drew up the Confession of Augsburg and was the author of textbooks for all disciplines known in his time, from theology to physics. For reforming the curricula of university and higher education, he was acclaimed the Praeceptor Germaniae.

Born at Bretten on February 16, 1497, Melanchthon studied under his uncle Johannes Reuchlin until 1509; at the University of Heidelberg until 1512; and at the University of Tübingen until 1514. In 1518, he was appointed professor of Greek at the University of Wittenberg, where he taught for 42 years, until his death on April 19, 1560.

As regards the language sciences, Melanchthon was recognized by Desiderius Erasmus as early as 1518 for his Greek grammar, which was followed by a Latin grammar (Melanchthon, 1834–1860, vol. 20, pp. 3–179, 193–336). In his dialectic (Melanchthon, 1834–1860, vol. 13, pp. 507–702), he combined into a new methodical unity Cicero's doxastic Topic, the Stoic notion of systema, and the Aristotelian theory of demonstration. The relation between humanist and traditional logic during the Renaissance is a central issue with respect to the impact of Melanchthon's logic. Like many humanist logicians of his time, Melanchthon took a disruptive and destructive stance against traditional treatments of logic, achieving the result of discarding the more technical aspects of medieval logic while shifting the center of attention to nondeductive inferences, good arguments (in the sense of arguments that can be counted on to win in debate), and the problematic nature of arguments' validity (Jardine, 1988). In his rhetoric (Melanchthon, 1834–1860, vol. 13, pp. 27–506), Melanchthon developed two complementary oppositions: on the one hand, that between a persuasive, eloquent mode of expression as against an arid, uninspired, and technical machinery; on the other hand, an adequate, rhetorical analysis of a text, treating it as a coherent whole as against the medieval approach, which chops a text into inarticulate little pieces, tearing it apart in order to proceed to a formal interpretation of the fourfold significance of an argument (Meerhoff, 1994).

"Prudent men have discovered through experience that nothing is more difficult than to speak clearly and distinctly about a given subject" (Melanchthon, 2000): Melanchthon's concept of an integration of philosophical grammar, dialectic, and rhetoric was in fact revolutionary, insofar as the invention becomes consciously subordinated to the philosophical claims of searching for truth (Schanze, 1983).

Melanesian Religions

M MacDonald, Le Moyne College, Syracuse, NY, USA

Melanesia is a region of the Southwest Pacific which stretches from Irian Jaya in the west through Papua New Guinea, the Solomon Islands, Vanuatu, and New Caledonia, as far east as Fiji. In 2004, its population numbered about eight million. Melanesians speak some 1200 languages, or, according to some estimates, one-quarter of the world's languages. These languages belong to two different groups, Austronesian and non-Austronesian (also called Papuan). The area is home to a number of pidgins, some based in English and others in French. There were trading languages in use in Melanesia prior to European contact,

and plantations and missions furthered their development as lingua francas. Melanesians live in small-scale societies, some of which are patrilineal and others matrilineal. They occupy varied habitats, including coral atolls, rainforests, and high mountain valleys, and their religious traditions embody their relationships to these environments. Most Melanesians are subsistence horticulturalists who supplement a diet of tubers and green vegetables with game or fish and keep pigs for ceremonial purposes. A few are primarily hunters and gatherers, while, over the course of time since first colonial contact, some have become town-dwellers who depend on wage labor for their sustenance. A desire to maintain life-giving relationships pervades the manner in which people interact with other people, with gods and spirits, and with the environment. Fertility – in the sense of the maximization of life force – is the major focus of the traditional religions and also of the Melanesian styles of Christianity and the new religious movements that have developed in the region.

People and Spirits

Traditional Melanesian societies conceived of the cosmos as a number of linked places inhabited by communities of various kinds. For the Kewa of the New Guinea highlands, for example, the cosmos included the distant world of the sky people, forests inhabited by various kinds of spirits, settlements of ghosts reached by taking paths through the forest, and settlements of human beings. Various terms – gods or deities, culture heroes, ancestors or ghosts, land spirits – have been used by anthropologists and historians of religion to approximate the indigenous names of the nonhuman inhabitants of Melanesian worlds. In local languages, they are often designated as people – sky people, forest people, cave people, cannibal people, and so on. The spirit beings are invisible under ordinary circumstances, but they have an existence parallel to that of human beings who will be referred to as the settlement or village people. In each local world, the particular inhabitants need to be understood in relation to the others with whom they interact. Morality which is based in kin relationships and local community includes appropriate behavior toward spirits and their habitats.

Culture heroes and gods are more significant in mythology than in everyday religious practice. Culture heroes, those mythic persons who gave rise to the physical and social world, are said to have shaped mountains and planted trees and to have instituted marriage and exchange relationships. Brother heroes, such as Kilibob and Manup in the myths of the Madang area of New Guinea, typically portray contrasting ways of life and behavior. Spirits responsible for creation and regulation of the world have been designated gods in the accounts of some ethnographers. The dead dwell in a settlement separate from that of the living – under the ground, in the sea, in the sky – to which they travel after death. They may return when invited on ritual occasions or when they deem it necessary to visit the settlements of their living relatives. At death, rituals mark the transition from life in the domain of the living to life in the domain of the ghosts. Traditional mortuary customs vary from burial in the family house to exposure on platforms in the forest to burial at sea. Following colonial and missionary contact, it became usual for bodies of the dead to be buried in cemeteries or at individual burial sites. After burial, further rituals sustain and nourish the relationship between living human beings and the dead. Traditionally, there were rituals for individual ghosts and others for the ghosts collectively; some families and communities maintain these celebrations. Such rituals involve the killing of marsupials and/or pigs and the sharing of food between living and dead. They also include speeches, singing, and dancing. The presence of ghosts invited to festivals is signified by the use of masks, drums, and flutes. People appeal to their own dead relatives for assistance in times of need. When the ancestors as a group are invited to participate in ceremonies, carved figures and masks may be produced to represent them. In some communities, masks and carvings are saved in a cult house, while in others they are discarded after the ceremonies when the ancestors are said to have returned to their own settlement.

Land spirits inhabit forests, grasslands, mountains, and swamps. Some are imagined as the inhabitants of particular trees or caves; others are construed as tricksters, monsters, or ogres, at least capricious, and potentially malevolent. People perform rituals and/or observe taboos when venturing into dangerous and isolated places where spirits are said to shoot arrows of affliction into trespassers and to trip up those who disturb them. Before making a change to their environment, such as felling a tree, people will placate spirits with gifts and politely entreat them to move to another place.

Oral Traditions and Ritual

Melanesian religious traditions are transmitted in the give and take of everyday conversation and work. They are also embodied in the metaphoric processes of storytelling and ritual. Oral traditions tell of the relationship of a community to a particular landscape. Stories narrate the exploits of known people, of mythic ancestors, and of gods and culture heroes. Narratives of events that took place in particular places serve to

transmit a system of land tenure. They also point to places of power where people should perform rituals. Traditionally, songs were composed for courting, for funerals, and for other occasions in personal and communal life. Word taboo and name taboo are practiced as means of protecting relationships, and in some areas religious argots are employed, as, for example, the special languages employed during the pandanus harvest in the Southern Highlands of Papua New Guinea (Franklin, 1972; Franklin and Stefaniw, 1992).

There are rituals for weather, gardening, childraising, attracting members of the opposite sex, hunting, fishing, pig husbandry, trade, warfare, and healing. Full-time ritual officiants are rare, but a variety of healers, mediums, and other practitioners devote part of their time to ritual practice, and everyone practices some rituals. Melanesians are competent gardeners with knowledge of plants and soils and seasons, but they are dependent on the weather and are at the mercy of insect pests. They express their desires for their gardens and their commitment to the work of gardening in spells and ritual. Garden spells invite the sun and rain to visit the garden and seek to cast out insects and disease. Prohibiting sex during the growing period or expecting a couple to have sexual relations in their new garden confirms the pervasiveness of fertility in all of life and the responsibility of humans to manage powerful relationships. Taboos regulate contact with persons, animals, foods, objects, and places; some clans have a taboo against consuming an animal associated with the clan.

Rituals are employed to encourage health and well-being of humans and to send away the forces which inhibit a good life. If a person is sick, a ghost, a land spirit, or a sorcerer or witch is blamed. Healers usually combine the works of healing and sorcery. They are engaged to divine the causes of illness, to prescribe remedies, which may be herbal or ritual or a combination of the two, and to carry out sorcery and counter-sorcery.

Many Melanesian societies have practiced initiation for boys and some for girls. However, following colonial contact and missionization, traditional initiation declined. In male initiation, boys are taken away from their mothers and secluded under the direction of senior men for weeks or months. Typically, they are required to observe food taboos, are instructed in ritual behavior, are taught songs and told stories. They may undergo scarification, tattooing, and incision of the foreskin. In many societies, boys are introduced to sacred flutes or bullroarers, which men use to produce the voices of the spirits. In some areas, introduction to the male cult and first participation in warfare is what makes a boy into a man, whereas in others an elaborate system of graded initiation is followed.

Rituals for females are usually linked to first menstruation and to marriage. As with boys, there are foods that girls should eat and foods they should avoid in order to develop the appropriate gender identity. Melanesian marriage rituals, most of which involve several stages, include the exchange of valuables between the families of bride and groom. Women generally have a repertoire of rituals and taboos to ensure the health and well-being of their children, their gardens, and the pigs entrusted to their care. These may be imparted to girls in a ritual context or learned in daily life. In many parts of Melanesia, a woman is expected to avoid her husband and members of his blood line at the time of menstruation. She will not prepare food for him lest her blood contaminate it and prove polluting or weakening to him.

Ritual is important in renewing social structures. In parts of Melanesia with hereditary chiefs (e.g., Fiji, New Caledonia, and the Trobriand Islands), first fruits ceremonies celebrate the people's relationship to a particular crop such as yams and also summarize the structure of the society. Yams are eaten in turn by priest, chief, men, women, and children, and exchanges of yams take place between individuals and lineages. The pattern of eating and exchanges mirrors the pattern of the society. Similarly, in the highlands of New Guinea, where leadership is not hereditary, ritual exchange in events such as the large-scale killing of pigs and transactions of pork and shells provides opportunity for renewal of community and cosmos.

Religious Change

Oral histories suggest that prior to colonial contact, which began in some areas in the late 19th century but did not reach other areas until after World War II, considerable change occurred in Melanesian religions. For example, cults were imported from one area to another. One may speculate that events such as the arrival of pigs from Asia some 5000 to 6000 years ago and the introduction of the sweet potato from South America some 300 to 400 years ago changed both the economic and symbolic life of Melanesian communities. In the colonial period, as Melanesians were recruited for labor in mines, plantations, offices, and factories, workers came in contact with the traditions of groups that differed from their own. In this period, Christianity in a variety of denominations began to be introduced to the region. The original colonial powers in the region (Germany, Britain, France, The Netherlands) saw missions as their allies in the spread of civilization. The people of Irian Jaya experienced the Dutch and later the Indonesians as colonial masters. Christianity was introduced in the Dutch period and Islam under Indonesian rule.

From the late 19th century, Protestant and Catholic missions entered Melanesia and became heavily involved in the work of health and education. Biblical stories and Christian rituals were assumed by those to whom the first missionaries preached to work in ways similar to indigenous myth and ritual. Melanesian Christians find commonalities in the themes of indigenous myths and biblical narratives, and students in the region's theological colleges will typically write their B.Div. theses on the relationship of indigenous and biblical texts. Some understand the Christian God as a fuller revelation of an indigenous god or spirit. Various Melanesian languages were employed as mission lingua francas, among them Kate, Yabim, Dobu, Kuanua, Motu, Suau, Wedau, Toaripi, Gedaged, Gogadola, Boiken, and Kiwai (McElhanon, 1979). Missionaries and, later, members of the Summer Institute of Linguistics studied indigenous languages and translated the Bible into them. The popular newspaper *Wantok*, in Tok Pisin, which was started by Catholic missionaries, and the publications of Kristen Pres, an agency of the Lutheran Church, point to the role of the churches in promoting the written word.

Religious movements in which participants await the arrival of an abundance of goods or anticipate a social utopia, were reported following colonial contact, and from the mid-1940s came to be known as 'cargo cults,' a term which may say as much about the colonial observers as about the Melanesian cultists. The movements probably had continuity with wealth rituals and exchange activities that were part of precolonial Melanesia. Taking elements from indigenous religions and from Christianity, they sought to attain a lifestyle characterized by wealth and good relationships. While classic cargo cults have waned in Melanesia, a plethora of religious movements and new churches continue to respond to changing circumstances and to communicate desires for Melanesian forms of religion. At the beginning of the 21st century, most Melanesians were Christians, with the style of Christianity depending on the nature of local traditions and the teachings and practices of the denomination which sent missionaries to the area. The ongoing conversation of Christianity and indigenous traditions is exemplified in the work of Melanesian writers such as Esau Tuza, Bernard Narokobi, and Simeon Namunu who advocate Melanesian forms of Christianity which build on indigenous understandings (Trompf, 1987), but there are also examples of the rejection of indigenous traditions in order to follow Christian ways (Robbins, 2004).

lexemes. In other words, there is no need for phrase-structure categories as syntactic information is located in the lexicon.

Currently the Meaning-Text Theory is gaining importance in several areas of formal linguistics and computational linguistics. It has been taken over by other formalisms, such as generative lexicon; since 2003, international conferences have been specifically dedicated to the developments in Meaning-Text Theory.

Memes

G Powell, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

In his 1976 book *The selfish gene*, the British zoologist Richard Dawkins proposed a new view on the nature of evolution. His overall claim was that evolution is driven not by species, nor by individual organisms, but rather by a more basic unit, the replicator, where a replicator is "anything in the universe of which copies are made" (Dawkins, 1982). His idea is that the engine of evolution is competition between distinct replicators, with a replicator's success determined, roughly speaking, by the number of copies it gives rise to. The most obvious of Dawkins's evolutionary replicators is the gene, the basic unit of biological evolution. But one of the insights offered by Dawkins's view was that evolution, viewed as an ongoing competition between self-propagating replicators, is not restricted to biology. For humans at least (and maybe in very limited respects for some other species), culture is also evolutionary: culture, just like biology, is a matter of the competition between particular replicators. But what are these cultural replicators? What is the cultural equivalent of the gene? Dawkins labeled it the 'meme.'

What Is a Meme?

Given the parallel with biological evolution, memes are defined as the basic units of cultural evolution. But what might they look like? They are essentially pieces of information, of whatever sort, which pass

from mind to mind via imitation. Moreover, given Dawkins's general view of evolution, they must be selfish: as Sperber (2000: 163) put it, they must stand "to be selected not because they benefit their human carriers, but because they benefit themselves." In *The selfish gene*, Dawkins suggested: "Examples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or of building arches" (1976: 206). Beyond these, the list of cultural elements which have been considered as memes is extensive. Dawkins (1976) himself suggested that both religious beliefs and language are memes, or rather complexes of interrelated memes. Other proposed candidates include chain letters, jokes, conspiracy theories, and sundry Internet phenomena. All of these seem, on the face of it, to propagate themselves via imitation, i.e., via the production of copies. Moreover, at least some seem clearly to do so in a way that benefits themselves, rather than their hosts. Chain letters, for instance, do not benefit those who reproduce them, and yet are highly successful replicators (see Dennett, 1990; Sperber, 2000).

How Are Memes like Genes?

This may seem on the face of it to be an unhelpful question. After all, for Dawkins, who coined the term, memes are essentially defined as the cultural equivalent of genes. From this perspective, the question we should really be asking is whether there are in fact memes in human culture. However, what I want to examine in this section is the extent to which those cultural items which have been identified as memes, either by Dawkins himself or by those who have developed memetics (the science of memes) in his wake, are genuinely similar to genes. Given the above discussion, there seem to be some clear parallels between genes and memes: in Dawkins's terms, both are replicators, i.e., both generate copies of themselves. It also seems as if the success of both in their respective replicator pools depends on similar factors. For Dawkins, two of the key factors which determine the success of a particular replicator are longevity and fecundity, i.e., how long particular copies of the replicator survive and how many copies each gives rise to. As Dawkins (1976) argued, these factors seem to determine the success of memes, in much the same way that they determine the success of genes. Moreover, just as with genes, it seems at least plausible that memes are selfish. As Dennett (1990) pointed out, there are many very successful memes which seem to be of no benefit other than to themselves: among the examples he suggested are anti-Semitism and computer viruses.

How Are Memes unlike Genes?

The above list of parallels between genes and those cultural items which have been identified as memes is certainly not complete. There are, however, some important respects in which memes seem not to be like genes. Along with longevity and fecundity, copying fidelity is a key factor in the success of genes. In other words, *ceteris paribus*, the more accurate the copies it produces, the more successful a gene will be. As Dawkins himself concedes, however, it would seem on the face of it as if copying fidelity is not such an issue for memes. Memes passed from host to host tend to undergo a high degree of variation. Consider, for instance, jokes: although we can identify a joke as the same as it passes from person to person via retelling, each retelling will differ in fundamental ways from its predecessor. Perhaps more significantly, there seems to be no memetic equivalent of the distinction between genotype and phenotype, a distinction which is fundamental to Darwinian theories of biological evolution. The idea, in very rough terms, is that the biological properties of each individual organism, i.e., its phenotype, is a function of two factors: the organism's genotype and its environment. What passes genetically from individual to individual is not the phenotype, i.e., not the specific biological properties of the parent organism, but rather the genotype: if a man accidentally loses a finger, his child will not be born with nine fingers. However, it seems that meme replication involves replication ofthe phenotype: changes in a particular copy of a meme will be transmitted to copies of that copy. Again, this list of differences between genes and memes is incomplete. Nevertheless, it suggests that maybe we should be cautious before taking the parallel between memes and genes as anything more than a useful metaphor.

The Current State of Memetics

The *meme* meme has itself been hugely successful. Although its original champions, in particular Dawkins himself and Daniel Dennett, seem to have retreated to some extent, there is no shortage of supporters to take their place. In particular, Blackmore (1999) has defended a thesis on which both the human brain and the self are products of the replication of successful memes. Given its evolutionary advantages, there seems no reason to suppose that this particular meme will not continue to flourish.

Mencken, Henry Louis (1880–1956)

J G Fought, Diamond Bar, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Henry Louis Mencken was born in Baltimore, Maryland, his lifelong home, residing for all but 8 years in a brick rowhouse at 1524 Hollins Street, now maintained as a museum by the Mencken Society. He was a prodigious writer: his works amount to about 10 million words.

His only academic distinction was graduation at 16 with high honors from a public high school, the Baltimore Polytechnic Institute. He left the family's cigar factory as soon as he could and became a reporter at the *Morning Herald*. In 1906 he joined the *Baltimore Sun*, thereafter remaining connected with the *Sun* papers except from 1917 to 1920, a hiatus brought on by his pro-German sympathies in World War I. His coverage of the Scopes trial in 1925, like his coverage of national political conventions and much of his other reporting, was as much cultural criticism as journalism. From 1914 he wrote for and co-edited *Smart Set*, launched by George Jean Nathan; together they started another influential literary magazine, *American Mercury*, in 1924.

In 1919, the first edition of his long, discursive study *The American language* was published by Knopf, which would publish three more editions, with multiple printings of each, and supplements that tripled its bulk over the next 30 years. In this monumental task, Mencken was aided by a newspaper clipping service, correspondents from all over the world, and some professional scholars as well, among whom Louise Pound (1872–1958) was conspicuous.

The texture of this book is hard to describe. It mingles citations from scholarly works with all kinds of other sources. It can still be found in libraries everywhere; the full text of the second (1921) edition can even be found online. Of course, Mencken's contribution to U.S. linguistics was most significant outside the academy, as he doubtless wished it to be. Against the strength of his name, the weight of his evidence, and his matchless invective, literary and academic detractors of this and his other works were powerless. The language that he wrote of, and wrote in, lived outside the academy, just as he did. *The American language* still rewards its readers, new and old, within minutes of opening it, whether to follow a thread for a time or just to browse among the masses of material, admiring the persistence that brought it all together, enjoying the seemingly spontaneous writing, and absorbing his respect for wit, independence, and vitality, as well as his contempt for pedantry and pretense. Most significant of all, it was H. L. Mencken who first made untold numbers of readers, from 1919 onward into the future, aware of language, our language, as an object of wonder and study.

Mencken, Henry Louis (1880–1956)

J G Fought, Diamond Bar, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Henry Louis Mencken was born in Baltimore, Maryland, his lifelong home, residing for all but 8 years in a brick rowhouse at 1524 Hollins Street, now maintained as a museum by the Mencken Society. He was a prodigious writer: his works amount to about 10 million words.

His only academic distinction was graduation at 16 with high honors from a public high school, the Baltimore Polytechnic Institute. He left the family's cigar factory as soon as he could and became a reporter at the *Morning Herald*. In 1906 he joined the *Baltimore Sun*, thereafter remaining connected with the *Sun* papers except from 1917 to 1920, a hiatus brought on by his pro-German sympathies in World War I. His coverage of the Scopes trial in 1925, like his coverage of national political conventions and much of his other reporting, was as much cultural criticism as journalism. From 1914 he wrote for and co-edited *Smart Set*, launched by George Jean Nathan; together they started another influential literary magazine, *American Mercury*, in 1924.

In 1919, the first edition of his long, discursive study *The American language* was published by Knopf, which would publish three more editions, with multiple printings of each, and supplements that tripled its bulk over the next 30 years. In this monumental task, Mencken was aided by a newspaper clipping service, correspondents from all over the world, and some professional scholars as well, among whom Louise Pound (1872–1958) was conspicuous.

The texture of this book is hard to describe. It mingles citations from scholarly works with all kinds of other sources. It can still be found in libraries everywhere; the full text of the second (1921) edition can even be found online. Of course, Mencken's contribution to U.S. linguistics was most significant outside the academy, as he doubtless wished it to be. Against the strength of his name, the weight of his evidence, and his matchless invective, literary and academic detractors of this and his other works were powerless. The language that he wrote of, and wrote in, lived outside the academy, just as he did. *The American language* still rewards its readers, new and old, within minutes of opening it, whether to follow a thread for a time or just to browse among the masses of material, admiring the persistence that brought it all together, enjoying the seemingly spontaneous writing, and absorbing his respect for wit, independence, and vitality, as well as his contempt for pedantry and pretense. Most significant of all, it was H. L. Mencken who first made untold numbers of readers, from 1919 onward into the future, aware of language, our language, as an object of wonder and study.

Menéndez Pidal, Ramón (1869–1968)

M Piot, Université Stendhal Grenoble 3, Grenoble, France

© 2006 Elsevier Ltd. All rights reserved.

Ramón Menéndez Pidal was a noted authority on Spanish epic literature, a major modern historian, and dominated Spanish linguistics in the first half of the 20th century. Born on March 13, 1869 in La Coruña, he moved to Madrid with his family in 1884. He studied law and literature under Menéndez Pelayo. In 1892, he earned his doctorate in philosophy and literature from the University of Madrid with a dissertation entitled *El conde de Lucanor* and in 1895 won the prestigious Academy prize with an essay on the *Cantar de mío Cid* (published in 1908). After a year at the University of Toulouse (France), where he studied Old French and Occitan, he moved to Spain and was appointed to the Chair of Romance Philology of the University of Madrid (1899). In 1902, he became member of the Real Academia Española and was twice head, until the civil war, of the Royal Spanish Academy (1929–1939 and 1948–1968). Founding editor in 1909 and head, until the civil war, of the *Centro de Estudios Historicos*, which focused on the Spanish language until the civil war, in 1914 he also founded and directed the *Revista de Filologia española*. During the civil war, he gave a series of lectures at the universities of Toulouse and Havana, Cuba, and then at Columbia University in New York, but returned to Spain as a private scholar until his death.

He gave new life to the study of medieval Spanish poetry and chronicles with his work on the origins of the Spanish language, as well as critical editions of texts, most of them translated into English, Russian, and French.

Among his studies in medieval literature are *El romancero español* (1910) and *Poesía juglaresca y juglares* (1924), as well as several works on El Cid. Menéndez's vast and meticulous research included monographs on folklore, literary history, the stylistics of Theresa of Avila, Lope de Vega, and others, and on etymology and place names.

The sources of Menendez's linguistic ideas were the neogrammarian model. With his positivist, meticulous methodology, he introduced the idea in Spain, giving rise to modern dialectal studies, but remained largely unknown in his own land. A Galician by origin, he always emphasized the primacy of Castilian in Spain, while he stressed the native roots of Spanish culture throughout all his works, including the Basque, Gothic, and Arab. *Orígenes del español* (1926) was followed by *La España del Cid*, 2 vol. (1929).

His monumental *Historia de Espana*, which he began to edit in the 1930s, was incomplete at the time of his death. Its introduction, however, *Los españoles en la historia y en la literatura* (1947), is one of his best-known and most accessible works.

The Basic Hypothesis

Some theorists of mind have claimed that thought takes place in a language-like medium. They have called this language 'Mentalese.' Mentalese has a syntax, a semantics, and a morphology, though discovering these properties of the language of thought will likely require extensive empirical investigation of the mind. Obviously, mentalese does not have a phonology. It is therefore more like written public language than overt speech. And whereas public languages require a pragmatics – a theory of how the language is used by speakers – mentalese, like the machine languages of computers, does not call for one.

Mentalese

F Egan, Rutgers University, Brunswick, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

The Basic Hypothesis

Some theorists of mind have claimed that thought takes place in a language-like medium. They have called this language 'Mentalese.' Mentalese has a syntax, a semantics, and a morphology, though discovering these properties of the language of thought will likely require extensive empirical investigation of the mind. Obviously, mentalese does not have a phonology. It is therefore more like written public language than overt speech. And whereas public languages require a pragmatics – a theory of how the language is used by speakers – mentalese, like the machine languages of computers, does not call for one.

Gilbert Harman (1973) offered the following argument for the existence of mentalese: logical relations hold among mental states, and these relations are essential to their role in psychological prediction and explanation. If the belief that *snow is white and grass is green* is true, then the belief that *snow is white* is true. In general, if the belief that *p & q* is true, then the belief that *p* is true. Generalizations of this sort presuppose that beliefs have sentential structure. Some beliefs are conjunctions, others disjunctions, and so on. Beliefs (as well as desires, fears, and the other propositional attitudes) are part of a language-like system.

Harman's argument fails to establish that mental states themselves have logical or sentential structure. The argument trades on the fact that belief **ascriptions** have sentential structure. We ascribe certain beliefs to subjects using sentences that are conjunctive or disjunctive, but it does not follow that the mental states so ascribed are themselves conjunctions or disjunctions, or that the relations that hold among these mental states are of the sort that hold among sentences (or propositions), that is, that they are logical relations. To assume that they are is just to assume what is at issue – that thoughts have a language-like structure. In general, one must guard against attributing to thoughts themselves properties of the representational scheme that we use to talk about them.

The hypothesis that thought occurs in a language-like medium is understood as the claim that not only beliefs but also desires and the other propositional attitudes are properly construed as relations to sentences in the inner language. To believe that the conflict in the Middle East will not be resolved is to bear a relation to an inner sentence token that means *the conflict in the Middle East will not be resolved*. To fear that the conflict in the Middle East will not be resolved is to bear a different relation to an internal sentence of the same type. The difference between the believing-relation and the fear-relation is construed as a difference in the processing that the sentence token undergoes in the brain, in other words, as a difference in its functional role. The belief is likely to cause, in certain circumstances, sincere assertions of a public language sentence meaning *the conflict in the Middle East will not be resolved*. The fear is more likely to give rise to appropriate emotional states.

What Is Mentalese Like?

The Thinker's Public Language, or a Proprietary Inner Code?

Some theorists have supposed that mentalese is just the thinker's own public language. English speakers think in English, Chinese speakers in Chinese. One might be inclined to this view by reflecting on the fact that many thoughts do not seem possible until the thinker has acquired a public language. Consider, for example, the thought that *the leech of the genoa is curled*. A subject cannot genuinely think this thought until she has acquired the concepts *leech* and *genoa*. Moreover, acquiring such concepts seems to require learning the appropriate public language terms for them, or more basic public language terms in which they can be defined. If mentalese is just the thinker's public language, then investigation of its properties is relatively straightforward. The syntax of an English speaker's mentalese is just English syntax; its semantics is just English semantics.

Jerry Fodor, in his groundbreaking 1975 book, *The language of thought*, argued that thought takes place in a proprietary inner code; moreover, this inner language has the expressive power of any public language a thinker is capable of learning. According to Fodor, the process of language learning involves hypothesis formation and testing; in particular, the hypotheses have the form of 'truth rules' for the application of the public language terms. To learn the English term 'genoa' is to learn a rule of the form "x is a genoa' is true if and only if x is P,' where P is a predicate in the proprietary inner language that is coextensive with the English predicate 'genoa.' To learn a public language is to acquire a translation manual that pairs terms in the language of thought with their public language equivalents. On pain of regress, terms in the language of thought are not themselves learned. A consequence of Fodor's view is that the concept *genoa* – and *electron*, *carburetor*, and any other concept a thinker can possess – is either innate or definable in terms of other concepts that are themselves innate. Fodor argues (Fodor, 1981) that few concepts are so definable; hence the vast majority of a thinker's concepts are innate.

Needless to say, many have found Fodor's extreme nativism unpalatable. His argument depends upon construing (public) language learning as hypothesis formation and confirmation, a process that requires an internal medium of representation, a language of thought where the hypotheses are couched. But there is nothing inevitable about explicit hypothesis formation and testing models of learning. If public language predicates were learned as a result of a causal process that is not construed as linguistic or inferential – a process sometimes known as 'triggering' – then the argument's nativist conclusion would not follow.

Whatever their views on concept-nativism, most proponents of the view that thought takes place in a linguistic medium have followed Fodor in claiming that the language of thought is an inner neural code,

distinct from any public language. Accordingly, we will hereinafter construe the 'language of thought hypothesis' (LOT) as the view that thought takes place in a proprietary inner code.

Psycho-Syntax and Psycho-Semantics

If the language of thought is indeed an inner neural code, then discovering its syntax and semantics will require extensive empirical investigation of the mind. Characterizing the syntax of mentalese will involve a specification of a finite set of primitive objects (words), and a grammar or set of formation rules that describe the ways in which complex syntactic objects (sentences) may be built out of the primitives. The individuation of syntactic types will be functionally based, adverting to the causal roles of these objects in the subject's cognitive life.

The so-called 'mental logic' research program that attempts to uncover the formal rules of inference underlying human deductive reasoning presupposes the existence of an innate syntax of thought and proposes to empirically investigate it. (See the papers in Braine and O'Brien, 1998.) Various candidate inference schemas have been offered, but no proposal is sufficiently detailed to generate empirically testable predictions regarding the underlying syntax.

A full theory of mentalese also requires a 'psycho-semantics' – an account of how internal sentences acquire their meaning. In virtue of what fact does a particular mental sentence mean *snow is white* rather than $2+2=4$? The meanings of public language sentences are fixed by public agreement, or derive in some way from the mental states of the users of these sentences, but, on pain of circularity, the sentences of mentalese must acquire their meanings in some other way. Since the 1980s, there has been a proliferation of theories, mostly by philosophers, purporting to explain how mental representation is possible. Not all of these accounts presuppose LOT, but most, if not all, are compatible with it. Typically, such theories attempt to explain the semantic properties of thought while respecting a naturalistic constraint – they attempt to specify sufficient conditions for a mental state's meaning, what it does in nonsemantic and nonintentional terms. (See Stich and Warfield, 1994 and **Representation in Language and Mind**.)

Further Arguments for LOT

Theories of Mental Processing Are Committed to LOT

Fodor (1975) reasoned that the only plausible models of mental processing are computational models, and that these require a medium of computation, that is, an inner system of representation. This argument has now been undermined by the existence of connectionist computational models. Connectionist machines are capable of performing cognitive tasks, but they lack fixed symbols over which computational operations are defined. Connectionist processes are not naturally interpretable as manipulations of internal sentences or data structures. If the mind is best characterized as a connectionist machine, or as an aggregate of such machines without an overarching executive control, then the LOT hypothesis is false.

LOT Explains Some Pervasive Features of Thought

Fodor (1987) argues that LOT provides the best, indeed, the only explanation of two pervasive features of thought. Thought is **productive**: we can think arbitrarily many thoughts. It is also **systematic**; cognitive capacities are systematically related. If a subject can think the thought *John loves Mary*, then he can think the thought *Mary loves John*. The explanation for the productivity and systematicity thought is that thoughts have a language-like structure. We can think arbitrarily many thoughts for the same reason that we can utter arbitrarily many sentences. Thoughts, like sentences, are composed of a finite base of elements put together in regular ways, according to the rules of a grammar. The systematicity of thought is also explained by LOT: systematically related thoughts contain the same basic elements but are arranged differently.

Whether the argument is successful depends on two issues: (1) whether productivity and systematicity are indeed pervasive features of thought; and (2) if they are, whether they can be accounted for without positing a language of thought.

Thoughts are assumed to be productive because they are represented, described, and attributed by public language sentences, a system which is itself productive. However, as noted above, one must be careful not to attribute to thoughts themselves properties of the representational scheme that we use to talk about them. It would be a mistake to think that temperature is infinite because the scheme used to measure it, the natural numbers, is infinite. If thoughts are understood as internal states of subjects that are, typically, effects of external conditions and causes of behavior, then it is not obvious that there are arbitrarily many of them. The size of the set of possible belief-states of human thinkers, like the size of the set of possible temperatures of objects, is a matter to be settled by empirical investigation.

Turning to systematicity, the argument falls short of establishing the existence of mentalese. In the first place, it is not clear how pervasive systematicity really is. It is not generally true that if a thinker can entertain

a proposition of the form aRb, then she can entertain bRa. One can think the thought *the boy parsed the sentence*, but not *the sentence parsed the boy*. Moreover, it is a matter of some dispute within the cognitive science community whether connectionist cognitive models, which do not posit a language of thought, might be capable of explaining the systematic relations that do hold among thoughts. (See MacDonald and MacDonald, 1995 for the classic papers on this issue, and Matthews, 1997 for further discussion).

Meringer, Rudolf (1859–1931)

A Cutler, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Rudolf Meringer's lasting contribution to linguistic science is that he first called attention to the linguistic significance of slips of the tongue. In two books, *Versprechen und Verlesen* (1895, co-authored with Carl Mayer) and *Aus dem Leben der Sprache* (1908), he published extensive collections of slips, with analysis and interpretation of their genesis; the books are still useful today.

Meringer was born in Vienna in 1859, studied at the University of Vienna, and taught there until 1899, when he became Professor of Indo-European Linguistics at the University of Graz. He died in 1931. The focus of his life's work was the history of words; with others (e.g., Hans Sperber, Hermann Güntert), he founded the philological school called cultural morphology, dedicated to the proposition that the history of words cannot be understood in isolation from cultural context. The movement reacted against what Meringer and colleagues perceived as the sterile formalism of Neogrammarianism, with resulting controversy (e.g., Schuchardt, 1911). Meringer was from 1909 founding editor of the movement's journal *Wörter und Sachen* and published many articles there; he also published a textbook of Indo-European linguistics (Meringer, 1897) that went into several editions. His *Wörter und Sachen* obituary (Güntert, 1932) did not mention his speech error work.

Meringer's speech error studies and the main body of his philological work were linked by his dedication to accurate observation as a research method. The error collections were compiled at the University of Vienna early in his career. Motivated originally by Hermann Paul's (1880) observations concerning similarities between speech errors and the processes of language change, Meringer's researches led him to reject the possibility that errors might actually precipitate sound change: "Speech errors and certain kinds of sound change are not inter-dependent. but share a higher cause in the nature of the psychological language organ" (Meringer and Mayer, 1895: vii). Four major generalizations may be extracted from his speech error writings: (1) Errors are not random but are rule-governed (Meringer, 1908: 3; Meringer and Mayer, 1895: 9–10); (2) the fundamental unit of speaking is not the speech sound but the word (Meringer and Mayer, 1895: 6–7); (3) words can be divided into structural components that differ in the strength of their internal representations (Meringer and Mayer, 1895: 164); (4) all speakers produce errors in the same way (Meringer and Mayer, 1895: 10; Meringer, 1908: 6, 123). These conclusions would all be accepted by psycholinguists working in this field today. For further detail of Meringer's error interpretations, see Cutler and Fay (1978).

Contrary to some later suggestions that attention to speech errors made Meringer unpopular, it is clear

a proposition of the form aRb, then she can entertain bRa. One can think the thought *the boy parsed the sentence*, but not *the sentence parsed the boy*. Moreover, it is a matter of some dispute within the cognitive science community whether connectionist cognitive models, which do not posit a language of thought, might be capable of explaining the systematic relations that do hold among thoughts. (See MacDonald and MacDonald, 1995 for the classic papers on this issue, and Matthews, 1997 for further discussion).

The error collections were compiled at the University of Vienna early in his career. Motivated originally by Hermann Paul's (1880) observations concerning similarities between speech errors and the processes of language change, Meringer's researches led him to reject the possibility that errors might actually precipitate sound change: "Speech errors and certain kinds of sound change are not inter-dependent. but share a higher cause in the nature of the psychological language organ" (Meringer and Mayer, 1895: vii). Four major generalizations may be extracted from his speech error writings: (1) Errors are not random but are rule-governed (Meringer, 1908: 3; Meringer and Mayer, 1895: 9–10); (2) the fundamental unit of speaking is not the speech sound but the word (Meringer and Mayer, 1895: 6–7); (3) words can be divided into structural components that differ in the strength of their internal representations (Meringer and Mayer, 1895: 164); (4) all speakers produce errors in the same way (Meringer and Mayer, 1895: 10; Meringer, 1908: 6, 123). These conclusions would all be accepted by psycholinguists working in this field today. For further detail of Meringer's error interpretations, see Cutler and Fay (1978).

Contrary to some later suggestions that attention to speech errors made Meringer unpopular, it is clear

that his colleagues warmly supported his error research. The greater part of his collection stemmed from lunchtime conversations among a regular group, whose support for the project was expressed in agreement that only one person should speak at once; when an error occurred, all conversation ceased until it had been recorded (Meringer, 1908: 5). However, contemporary reactions to Meringer's error books were mixed (see Cutler, 1979 for details). Sigmund Freud's use of examples from *Versprechen und Verlesen* in *The psychopathology of everyday life* (1901) did not meet with Meringer's approval (Meringer, 1908: 129–130; Meringer, 1923).

Meronymy

M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Meronymy (sometimes also called partonymy or the HAS-A relation) is the PART-OF relation. For example, *page*, *cover*, and *spine* are meronyms of *book* (in its physical-object sense) in that they are parts of books. The converse relation, that of whole to part, is sometimes called *holonymy*, but *meronymy* is often used to refer generally to the phenomenon of relatedness of expressions for wholes and parts. While meronymy is often mentioned, along with synonymy, antonymy, and hyponymy, in lists of semantic relations among words, lexicology have traditionally paid it less attention than the other relations, as meronymy is not so clearly a linguistic relation. This is to say that the relation is not clearly a lexical relation (relating words), nor a sense relation (relating the meanings of words), but rather is a relation among the referents that the expressions denote. For instance, while a tail is a part of a dog, 'tail' is not necessarily part of the meaning of *dog*, nor 'dog' part of the meaning of *tail*. Recent changes in approaches to meaning have resulted in more attention to meronymy, and the relation is relevant to several applied linguistic endeavors. For instance, the PART-OF relation (like the TYPE-OF relation, hyponymy) is central to the creation of dictionary definitions. Furthermore, different kinds of meronym relations are often represented in lexical knowledge databases created for Natural Language Processing projects (e.g., WordNet – see Miller, 1998). Definitions, properties, and subtypes of meronymy are discussed in turn below, followed by discussion of its treatment in contemporary linguistics. The signs < and > are used here to indicate meronymy, with the holonym on the open side of the symbol and the meronym on the pointed side – e.g., *bird>wing*, *finger<hand*.

Definition of Meronymy

Meronymy is often classed with hyponymy as an inclusion relation. It is typically defined in terms of the potential to put two expressions into a natural language frame like *An X is a part of (a) Y* or *a Y has X(s)/an X* and interpret the sentences as generically true (Cruse, 1986). So, for example, *bird>wing* passes these tests (*A wing is a part of a bird*; *A bird has a wing*) because the test frames express propositions that are considered to be generally true of birds (the existence of a few deformed birds notwithstanding). The particular test frames chosen affect what counts as meronymy to a particular theorist. For

that his colleagues warmly supported his error research. Meronymy (sometimes also called partonymy or the HAS-A relation) is the PART-OF relation. For example, *page*, *cover*, and *spine* are meronyms of *book* (in its physical-object sense) in that they are parts of books. The converse relation, that of whole to part, is sometimes called *holonymy*, but *meronymy* is often used to refer generally to the phenomenon of relatedness of expressions for wholes and parts. While meronymy is often mentioned, along with synonymy, antonymy, and hyponymy, in lists of semantic relations among words, lexicology have traditionally paid it less attention than the other relations, as meronymy is not so clearly a linguistic relation. This is to say that the relation is not clearly a lexical relation (relating words), nor a sense relation (relating the meanings of words), but rather is a relation among the referents that the expressions denote. For instance, while a tail is a part of a dog, 'tail' is not necessarily part of the meaning of *dog*, nor 'dog' part of the meaning of *tail*. Recent changes in approaches to meaning have resulted in more attention to meronymy, and the relation is relevant to several applied linguistic endeavors. For instance, the PART-OF relation (like the TYPE-OF relation, hyponymy) is central to the creation of dictionary definitions. Furthermore, different kinds of meronym relations are often represented in lexical knowledge databases created for Natural Language Processing projects (e.g., WordNet – see Miller, 1998). Definitions, properties, and subtypes of meronymy are discussed in turn below, followed by discussion of its treatment in contemporary linguistics. The signs < and > are used here to indicate meronymy, with the holonym on the open side of the symbol and the meronym on the pointed side – e.g., *bird>wing*, *finger<hand*.

Definition of Meronymy

Meronymy is often classed with hyponymy as an inclusion relation. It is typically defined in terms of the potential to put two expressions into a natural language frame like *An X is a part of (a) Y* or *a Y has X(s)/an X* and interpret the sentences as generically true (Cruse, 1986). So, for example, *bird>wing* passes these tests (*A wing is a part of a bird*; *A bird has a wing*) because the test frames express propositions that are considered to be generally true of birds (the existence of a few deformed birds notwithstanding). The particular test frames chosen affect what counts as meronymy to a particular theorist. For

example, Winston *et al.* (1987) propose that meronym relations include any that can be expressed using the term 'part' or derivations from it, such as *Y is partly X*. This allows for relations such as *metal<hammer*, as in *A hammer is partly metal*, while Cruse's test frames above do not naturally allow for materials to be in meronym relations to wholes. All of these frames for testing for meronym relations assume that meronymy holds between nouns. For instance, the gerund *swallowing* is in a meronym relation to *eating* (*Swallowing is a part of eating*), but the verb forms *swallow* and *eat* are generally not said to be meronyms, since they do not fit into the diagnostic frames (*?To swallow is partly to eat; ?To swallow is a part of to eat*).

Types of Meronyms

At one level, meronyms can be divided into two types: 'necessary' and 'optional' (Lyons 1977), otherwise called 'canonical' and 'facilitative' (Cruse, 1986). An example of necessary meronymy is *eye<face*. Having an eye is a necessary condition of a well-formed face, and even if it is removed, an eye is still a face part. Optional meronymy includes examples like *cushion<chair* – there are chairs without cushions and cushions that exist independently of chairs.

In addition to necessity, Cruse (2000) identifies four other dimensions on which meronym relations may differ. Some parts are more 'integral' to their wholes than others; compare *handle<door* and *handle<spoon* – without the handle, the spoon is not much of a spoon, but a door without a handle is still a door. Similarly, some parts are more 'discrete' than others; *tastebud* is a more discrete meronym of *tongue* than *tip* is, as its boundary is clearer. For some parts we have more motivation to name them, especially if that motivation is functional – the part is useful for some purpose. So, even though a *fingertip* has a fuzzy boundary, we are motivated to identify it as a part because it is useful. Finally, meronyms differ in their congruence, in three ways. 'Range congruence' is whether or not the meronym is more or less general in its range of reference than the holonym. A relatively congruent case is *navy>admiral*, since any navy has an admiral and there are not admirals without navies, whereas *door>handle* is quite range-incongruent, as some handles are not door handles and some doors have no handle. 'Phase congruence' is whether or not the parts exist in the same time. For example, in one sense, milk can be a part of a cake, but once it is a cake, the milk might be said not to exist anymore, so *cake>milk* is phase-incongruent. Finally, 'type congruence' holds when the part and whole are of the same ontological type, for example both being substances or objects. So, *biscuit>flour* is not very type-congruent in that the whole is a countable object, whereas the part is a substance. Cruse has used these features of meronym relations to distinguish between prototypical and nonprototypical meronym relations – claiming that the most prototypical meronyms are necessary, integral, discrete, motivated, and congruent.

Others have been motivated to distinguish between PART-OF relations in order to represent such relations directly in models of lexical knowledge. For instance, a cake can have slices, flour, and icing, but each of those involves a different kind of relation to the cake – i.e., the cake **is divided into** many slices, its **ingredients** include flour, milk, eggs, butter (etc.), and it **is constructed of** cake layers, icing, and possibly other fillings and toppings. How many types of relation any particular theorist names depends in part on how broadly they define the relation in the first place (e.g., using the *partly* diagnostic frame or not). Identified types include WHOLE>SEGMENT (*year>month*), WHOLE>FUNCTIONAL COMPONENT (*computer>keyboard*), COLLECTION>MEMBER (*forest>tree, club>member*), and WHOLE>SUBSTANCE (*jar>glass*). (See Iris *et al.*, 1988, Chaffin, 1992, and Miller, 1998 for particular taxonomies.)

Winston *et al.* (1987) base their taxonomy of meronym types on three binary features, which in different combinations describe the various types of meronymy: (+/−) FUNCTIONAL, (+/−) HOMEOMEROUS, and (+/−) SEPARABLE. If a relation is [+HOMEOMEROUS], then the part is made of the same kind of thing as the whole, as for *slice<pie* (versus *crust<pie*, which is non-homeomerous, since a pie has more ingredients than a crust). Separability is whether or not the part can be removed from the whole. So, SUBSTANCE<WHOLE relations are [−SEPARABLE], but MEMBER<COLLECTION relations are [+separable]. Based on this, they identify six types of relation out of a possible eight combinations of features – no type is both [+FUNCTIONAL] and [+HOMEOMEROUS].

Other types are identified in Meaning-Text Theory (MTT; Mel'čuk, 1996), an approach rooted in the quest for machine translation. Some of these types are SOCIAL WHOLE>STAFF (e.g., *ship>crew*), ORGANIZATION>HEAD (*ship>captain*), COLLECTION>MEMBER (*fleet>ship*), and WHOLE>CULMINATION/CENTER (*joke>punchline*). MTT also allows for the combination of lexical functions (such as the above relations) to create additional relations.

Properties of Meronymy

Because of the diversity of types of PART-OF relations and because the relations seem to relate referents

rather than senses, little can be said in general about logical properties of meronymy. Unlike synonymy and antonymy, the relation is asymmetrical; that is, words are not each other's meronyms. The various types of meronymy vary in whether they are transitive or not. For example, body parts are in transitive meronymic relations, as in (1).

(1) An eye is a part of a face.
A face is a part of a body.
∴ An eye is a part of a body.

But the cases in (2) and (3) seem less transitive.

(2) Bark is part of a tree.
A tree is part of a forest.
?∴ Bark is part of a forest.

(3) The house has a door.
The door has a handle.
?∴ The house has a handle. (Lyons, 1977)

Transitivity fails in (2) because the meronym relations in the premises are of different subtypes; *bark* <*tree* is COMPONENT<WHOLE, whereas *tree*<*forest* is MEMBER<COLLECTION.

Thus, transitivity failure is sometimes used as a diagnostic tool to determine subtypes of meronymy. In (3), both of the premises seem to involve the same relation: FUNCTIONAL COMPONENT<WHOLE. In this case, transitivity failure does not seem to be because of different types of meronym in the premises. Lyons (1977) distinguishes between (1) and (3) on the basis that (1) involves necessary meronymy (an eye is definitionally a face/body part) and (3) involves optional meronymy (a handle is not necessarily a door part). Since a handle can be a functional part of many different kinds of things (doors, cups, bags, hammers), the conclusion *The house has a handle* leads one to understand that the handle is for holding or moving the house, rather than holding or moving a house part.

Meronymy in Linguistic Theory

In recent decades, semantic theories have become less concerned with logical relations among words and propositions and more focused on the interface between language and mind. Whereas formerly meronymy could be considered a part of encyclopedic (rather than definitional) knowledge, the distinction between mental lexicon and mental encyclopedia has faded to nothing in many approaches, thus meronymy has renewed importance in the modeling of lexical meaning. Cognitivist approaches to meaning eschew the distinction between definitional and encyclopedic information and embrace the notion of prototypicality in meaning – that is, that meanings are not composed of strict conditions on reference, but rather are based on notions of ideal or exemplary instances of a category. As such, meronymic relations like *cat*>*tail* can be included in the representation of the meaning of *cat*, since doing so does not entail that anything called a cat must have a tail.

Current interest in meronymy is also motivated by computational linguistic projects. For instance, the types of meronymy represented in the MTT lexicon are of particular use in text generation. These relations constitute syntagmatic as well as paradigmatic relations, in that they frequently occur in phrases such as *the punchline of the joke* and *the fleet of ships*.

Mesoamerica: Scripts

J Marcus, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Sometime between 1000 and 600 B.C., hieroglyphic writing began to appear in Mexico. It spread and developed until, by A.D. 600–800, writing could be found throughout the region of high cultures known as Mesoamerica (Mexico, Guatemala, Belize, El Salvador, and Honduras). Writing reached its peak of complexity among the lowland Maya civilization of A.D. 292–909. For most of the contributors to this encyclopedia, only the Maya system of signs would qualify as true writing, but since the other Mesoamerican scripts are usually called 'writing,' I retain that designation here. All these scripts are related to one another, but since several different language families are involved, it remains for future investigators to untangle the specific relationships.

The Motivation for Mesoamerican Writing

Some ancient civilizations – the Inca, for example – seem not to have needed writing. This raises the question of why Mesoamerica needed it. Of all the Old World civilizations, the closest analogy to Mesoamerica seems to be Egypt. In both regions, the early use of writing was to label people and places in scenes that featured rulers, conquests, and prisoner taking. In Egypt, the Narmer Palette commemorated a ruler named Narmer, his prisoners, and his conquests. In Mexico, the oldest Zapotec monument gives the name of a slain captive (Flannery and Marcus, 2003). In the later Egyptian state, the "hieroglyphic writing system was improved for purposes of high culture and display rather than for administration; but the latter no doubt also exploited such developments" (Baines, 1999). Classic Maya states also used hieroglyphic texts to extol the deeds of rulers and to legitimize their right to rule, linking them to both royal ancestors and supernatural beings (Marcus, 1992). The origins of writing in both Egypt and Mesoamerica, therefore, contrast with that in Mesopotamia, where keeping economic records seems to have been the principal motivation and where tokens, not iconography, are claimed to have been the precursors of writing.

The Nature and Variety of Mesoamerican Writing Systems

In order to distinguish Mesoamerican writing from its iconographic precursors, we can list four requirements:

1. There must be at least three glyphs, arranged in a row or column.
2. The arrangement must determine reading order.
3. The set of glyphs must show a correspondence to the spoken language.
4. As a consequence, the arrangement must follow grammatical rules.

At least five principal writing systems appeared in Mesoamerica. The earliest was the Zapotec system of the southern Mexican highlands, followed by the Isthmian system to the south and east. Then came the Maya system, which was the most capable of capturing the spoken language. Much less complex were the later Mixtec and Aztec systems of the Mexican highlands, which were still in use when Europeans arrived in the New World. In addition to these five major systems, there were localized scripts, like those seen at the ancient cities of Teotihuacán, Xochicalco, and Cacaxtla in the Mexican highlands.

The Precursors of Mesoamerican Hieroglyphic Writing

The period 1150–850 B.C. was one of flamboyant societies with hereditary rank and sumptuary goods. Many portable artifacts of that period, such as pottery and jades, bore complex iconography. One popular medium for such iconography – especially in the Basin of Mexico near present-day Mexico City – were ceramic stamps, which could be coated with paint and rolled over cloth or the human body, producing a continuous strip of decoration. More than 300 of these stamps have been recovered at the site of Tlatilco alone (Field, 1967).

Forty-five years ago, José Luis Franco (1959) drew attention to a roller stamp from Tlatilco that featured three glyphs in a row (Figure 1). That sequence of glyphs is a tantalizing precursor to writing, because

Figure 1 This ceramic roller stamp includes three signs that seem to function as logograms. The profile head at A matches depictions of Earth; B is an abstract sign for Earth and the four world directions; the sign at C went on to become the Maya glyph *k'in*, meaning Sun/Day/Time (redrawn from Franco, 1959). Signs on such roller stamps, such as this one from the early village of Tlatilco in Mexico, may be forerunners of writing.

each glyph seems to be a logogram. This trio of signs falls short of writing only because we cannot show that it is a phrase or sentence that follows the grammatical structure of a known language.

Dating to ca. 1000 B.C., this potential precursor is intriguing because roller stamps were so much more common in the central Mexican highlands than in the lowland Isthmian or Maya regions. A few Tlatilco-style roller stamps with potential glyphs (or pseudo-glyphs) were traded to highland Oaxaca by 1000 B.C. and eventually to the Gulf Coast by 500–400 B.C. (uncalibrated) (Pohl *et al.*, 2002), but nowhere were they as abundant as in the central highlands of Mexico.

Why did the people of Mesoamerica move from iconography to writing? Given some of the earliest texts (see below), we suspect that scenes and iconographic symbols proved insufficient for writing proper nouns (the names of specific leaders and elite captives) and for recording the specific date of an event. The Zapotec, who were the earliest to write pure texts, did so in the context of endemic chiefly competition. Indeed, writing was born of that competition and became a tool in later rivalries among kings.

The Earliest Glyphs Carved in Stone

At the moment, the earliest known Zapotec glyph is a day name from the 260-day calendar (described below). The day name is that of a sacrificial victim carved on a stone slab serving as the threshold for a corridor between two temple platforms at the site of San José Mogote in the Valley of Oaxaca, Mexico (Figure 2). Two glyphs between his feet give his name as 'One L' (letters of the alphabet were assigned to Zapotec glyphs by Alfonso Caso in 1928). This monument was sealed stratigraphically below two hearths with uncalibrated dates of 630 and 560 B.C. (Flannery and Marcus, 2003). The first 'pure' texts (i.e., columns of glyphs unaccompanied by scenes) were carved on Stelae 12, 13, 15, and 17 at Monte Albán in the Valley of Oaxaca ca. 500–400 B.C. (uncalibrated) (Marcus, 1983).

At roughly the same time as these stelae, Monument 13 of La Venta in the Isthmian lowlands displayed a column of three glyphs; this is not a pure text, however, since it is accompanied by the figure of a man (Figure 3). Unfortunately, we do not know what language is represented by the Monument 13 glyphs. Behind the man is an isolated footprint, probably a logogram for 'journey.' Similar footprints are

Figure 2 Monument 3, San José Mogote, Valley of Oaxaca, Mexico, shows a slain captive whose 260-day calendar name is given between his feet. This monument dates to ca. 600 B.C. (uncalibrated). Both the riser and the tread of the threshold are carved; the tread shows the naked victim with his heart removed and two stylized drops of blood (circle + triangle) flowing down the riser (adapted from Marcus, 1992).

Figure 3 Monument 13, La Venta, Mexico, shows a column of three hieroglyphs, none of which provides calendric information. The third sign, possibly a bird's head, may provide part of the man's name. The footprint behind him is probably a logogram for 'travel' (redrawn from Marcus, 1992). Based on radiocarbon samples and stratigraphy, this monument may have been carved ca. 500–400 B.C. (uncalibrated).

featured on more than 50 roller stamps from two highland sites, Tlatilco and Las Bocas (Field, 1967). Those two sites are sufficiently older than Monument 13 as to frustrate any attempt to attribute the origins of writing to the Olmec culture of the Gulf Coast.

The Link between Writing and Calendar

From its inception, Mesoamerican writing was linked to one or more calendars. Dates gave specificity to events such as birth, death, marriage, conquest, accession to the throne, building dedications, and ritual offerings. All calendars featured combinations of number + day name. The two key calendars were the 260-day ritual calendar and the 365-day secular calendar.

The Mesoamerican counting system was based on units of 20 (*vigesimal system*). From 600 B.C. to 50 B.C., those groups with writing used two elements to express numbers – a dot with the value of 1 and a bar with the value of 5. By combining dots and bars, they could express any number from 1 to 19 (Figure 4). After 50 B.C. in the Isthmian and Maya regions, positional value notation and a sign for 'zero' or 'completion' were added to the repertoire. After A.D. 900 some groups, such as the Mixtec, went over to the exclusive use of dots (thus, 13 could be expressed as 13 dots, rather than 2 bars and 3 dots).

Figure 4 Two systems of numeration were used in Mesoamerica: the 'bar and dot' system (by the Zapotec, Isthmian groups, and Maya) and the 'all dot' system (by the Mixtec and sometimes by the Aztec) (redrawn from Marcus, 1992).

The Sacred Calendar The 260-day ritual calendar, which combined 13 numbers with 20 day names, was called *piye* by the Zapotec and *tonalpohualli* by the Aztec; this 260-day calendar was used by every linguistic group in Mesoamerica. That fact suggests to many scholars that the 260-day calendar had great time depth and may in fact have been used by the common ancestors of most Mesoamerican groups before their languages diverged.

The 260-day calendar had ritual functions, one of which was the naming of children after the day on which they were born. Thus, texts refer to individuals named 8 Deer, 5 Flower, 11 Crocodile, and so on. A study by Whallon (1992) of more than 2500 Mixtec names, however, suggested that parents avoided naming their children after inauspicious days by choosing the next auspicious day.

The Secular Calendar The secular calendar consisted of 18 'months' of 20 days ($18 \times 20 = 360$) + 5 extra days. This calendar was called *yza* by the Zapotec, *xihuitl* by the Aztec, *cuiya* by the Mixtec, and *haab* or *tun* by the Maya.

Combining Both Calendars When the 260-day and 365-day calendars were combined, a 52-year 'Calendar Round' of 18 980 differently designated days resulted. Each year of the Calendar Round was named after the day the year began, and that year name repeated itself every 52 years. To anchor dates more securely in time, the Isthmians developed a base date; later, the Maya used the same base date.

The 'Long Count' from a Base Date The system devised by the Isthmian and Maya cultures involved numeration by position, the mathematical concept of zero, and a base date to anchor events in time. From that base date, they calculated the number of days that had elapsed and used five units of time to do so (see Table 1).

The base date or starting point was September 8, 3114 B.C., which corresponded to the completion of 13 *Bak'tun* (13.0.0.0.0) and the beginning of *Bak'tun* 1 (1.0.0.0.0). The earliest use of this base date occurred outside the Maya region. Stone monuments

Table 1 Components of a Maya 'Long Count' date

1 cycle or *bak'tun* =	20 *k'atun* =	144 000 days (units of ca. 400 years)
1 *k'atun* =	20 *tun* =	7200 days (units of ca. 20 years)
1 *tun* =	18 *winal* =	360 days (year)
1 *winal* =	20 *k'in* =	20 days (month)
1 *k'in* =		1 day (day)

carved between 36 B.C. and A.D. 36 at Chiapa de Corzo (Mexico), Tres Zapotes (Mexico), and El Baúl (Guatemala) are among the earliest to use the base date (Marcus, 1976a). Later, the Maya elaborated temporal cycles even grander than the *bak'tun*. These cycles, some of which were used to place events far back in mythological time, included the *piktun* (20 *bak'tun*, or 8000 years), *kalab'tun* (20 *piktun*, or 160 000 years), *k'inchiltun* (20 *kalab'tun*, or 3 200 000 years), *alawtun* (20 *k'inchiltun*, or 64 million years), and even higher units.

We have spent this time on esoteric aspects of the calendar because it figures so importantly in Mesoamerica's hieroglyphic texts. We will now look at each of the five principal writing systems.

Zapotec Writing

Zapotec writing, currently the earliest, was a 'mixed' system in that it included pictograms (picture signs), logograms (word signs), and phonograms (sound signs). Although it had long been suspected that Zapotec hieroglyphic texts reflected the syntax of spoken Zapotec, it has only recently become possible to demonstrate this.

Ancient Zapotec texts provided calendrical, political, genealogical, and ritual information. The early monuments depicted people and supplied their calendar names; later texts supplied place names, gave information on ritual and political events, and displayed noble genealogies. As we have seen, by 500–400 B.C. (uncalibrated), the Zapotec had begun to carve monuments with columns of glyphs. Geographic place names made their appearance after 100 B.C., when they were used to list territories claimed along the frontier of the expanding Zapotec state. From A.D. 100 to 600, the Zapotec continued to give the names of elite captives, their hometowns, and the dates of their capture.

A major change in subject matter and format occurred after A.D. 600. The Zapotec capital, Monte Albán, was then declining in power, and its formerly subordinate towns were creating their own alliances. Nobles began to commission stone carvings to record their ties, by descent or marriage, to nobles at other sites in the Valley of Oaxaca. Much of the dynastic and ritual information was presented on a new type of monument, the *genealogical register*, whose format and content foreshadowed the later polychrome codices, or 'books,' commissioned by Mixtec rulers from A.D. 1200 to 1600 (Marcus, 1992; Smith, 1973; Urcid, 2001).

Let us now look at some details of Zapotec writing. Zapotec is a 'verb initial' language, meaning that verbs begin sentences and precede subjects. For example, the English sentence 'Lord 1 Crocodile, the first-born son, was born' would have been spoken in 16th-century Zapotec as: **was born** (*cale* or *cole*) + **firstborn** (*yobi*) + **lord** (*coqui*) + **1 Crocodile** (*quiechilla*). The word order would thus be verb + birth order + rank + day name of that lord. Sixteenth-century Spanish accounts tell us that name clauses could have included as many as five elements: (1) a rank term, such as lord (*coqui*), lady (*xonaxi*), or noble (*joana*); (2) a nickname (e.g., *Pechetào*, Great Jaguar); (3) birth-order position; (4) a 260-day calendar name; and (5) a hometown (especially for women who had married into another dynasty).

Birth-order position was indicated by ordinal numbers, depicted in Zapotec texts with fingers (or a hand with raised fingers). This is an example of the 'rebus principle.' (A well-known example in English is using a picture of an 'eye' to express the difficult-to-depict 'I.') In spoken Zapotec, the term for each finger was the same as that used for birth order. Thus *yobi* meant both 'first-born son' and 'thumb of the right hand'; *tini* meant second-born son and index finger; *texi*, third-born son and third finger; *payo*, fourth-born son and fourth finger; *yee*, fifth-born son and fifth finger. Different terms were used to indicate the birth order of daughters.

Now let us look at two clauses that illustrate Zapotec syntax and use fingers for birth order (Figure 5). The clauses of this stone, which was carved between A.D. 600 and 800 and placed in a royal tomb in the Valley of Oaxaca (Miller, 1995), include the following: date + verb (was born) + rank + subject's name + birth-order position + death + death date. Although the word order of these clauses is not common in all parts of the valley, an almost identical example can be found in a 16th-century genealogy from the district to which Suchilquitongo belongs. The discovery of such continuities will enable us to make progress in the study of the Zapotec writing system, whose decipherment is still in its infancy.

Isthmian Writing

The Isthmian script has been known since 1902, when the jade Tuxtla Statuette was found in Veracruz. This script was also known from a handful of portable objects and stone monuments, but in no case were the texts long enough to permit extensive study. All that changed in 1986 with the discovery of a stone monument at La Mojarra, Veracruz. That monument bears a text of 535 glyphs – the kind of long inscription epigraphers dream about, because the chance for decipherment increases dramatically when signs and phrases repeat themselves (Macri and Stark, 1993;

Figure 5 Two Zapotec clauses with similar syntax provide the names, as well as birth dates and death dates, for two individuals – (1) a daughter named 12 N, who was the third-born (*nijo*); and (2) a son named 12 O (12 Monkey) who was the fourth-born (*payo*). These clauses were carved on the sides of a stone that had been placed in a royal tomb at Suchilquitongo, Oaxaca, Mexico (redrawn from Miller, 1995). (The letters M, N, and O were assigned to these day-signs by Caso, 1928.)

Méluzin, 1995). Unfortunately, controversy rages over whether this text has really been translated. Two scholars have published what they believe is a translation, linking the text to the Mixe-Zoque language family (Justeson and Kaufman, 1993). Two other scholars, Houston and Coe (2003), remain unconvinced, asserting that they have plugged in Justeson and Kaufman's values to a newly discovered inscription, but "the inserted values yield a semantic mish-mash." This controversy is likely to continue into the foreseeable future.

The only part of the La Mojarra text on which all scholars seem to agree is the calendrics. The Long Count dates on the La Mojarra monument are A.D. 143 and 156, reasonably close to the A.D. 162 date incised on the Tuxtla Statuette. Although Isthmian and Maya texts used the same base date, the Isthmian Long Count dates preceded by 130 years the earliest Maya Long Count date (October 14, A.D. 292, which is recorded on Stela 29, Tikal, Guatemala).

Maya Writing

As with earlier Mesoamerican scripts, Maya texts often served as captions below people and objects in scenes. Such texts might supply (1) the names of lords and ladies at key Maya cities; (2) the exact dates of events; and (3) descriptions of actions such as prisoner taking (Figure 6), ritual offerings, bloodletting, the honoring of ancestors, and the naming of buildings. Many monuments provide dates for the birth, marriage, accession, death, and major events in the lives of ancient rulers; some texts even link these rulers to mythological forebears (Marcus, 1976b, 1992; Martin and Grube, 2000; Schele and Mathews, 1998). Painted texts on pottery sometimes provide information on the former contents and noble owner of the vessel and may even show nobles receiving visitors, as well as gifts and tribute (Reents-Budet, 1994).

Which of the 35 Mayan languages were represented by the script? More than 50 years ago, Thompson (1950) suggested that the script recorded a form of Cho'lan, a language family whose speakers extended from eastern Mexico to Honduras. Today we can be more specific and say that the inscriptions were written in an ancestral form of Ch'olti' and Ch'orti' (Chortí), the latter of which is still spoken today in Western Honduras. ('Mayan' usually refers to the language, while 'Maya' refers to the people and their civilization.)

Of all Mesoamerican writing systems, that of the Maya displayed the closest correspondence to the spoken language and the greatest degree of phoneticism. The Maya could write complete sentences,

Figure 6 In A.D. 755 a ruler from the Maya capital of Yaxchilan, Mexico, is aided by a provincial ruler in the taking of prisoners. Bird Jaguar of Yaxchilan (on the right) takes a prisoner named Jeweled Skull; the subordinate lord K'an Tok Wayib' (on the far left) takes a noble prisoner named Ko' Te' Ajaw (adapted from Marcus, 1992). (Labels written in all caps refer to logograms, while labels written in lowercase refer to phonetic elements.)

using signs that represented verbs, nouns, adjectives, prepositions, and pronouns. Approximately 800 signs are known; some are considered 'main signs' and others 'affixes' (Harris and Stearns, 1997; Macri and Looper, 2003). Main signs were usually whole words or word stems (Figure 7). Affixes of various kinds (prefixes, suffixes, infixes, superfixes, or subfixes) were added to those main signs to supply adjectives, tense, possession, prepositions, and so forth.

Like Zapotec and Isthmian scripts, Maya writing was logosyllabic, but the Maya relied much more heavily on phoneticism than those two earlier scripts. Maya texts could be 50% logographic and 50% phonetic. As more of the phonetic signs are deciphered, a

Figure 7 Example of a main sign surrounded by affixes. At left, the Palenque emblem glyph; at right, a diagram that labels all the elements seen at left (plus, the diagram shows where an infix can occur) (adapted from Marcus, 1992).

Figure 8 Maya syllabary recorded by Diego de Landa from Yukatek informants in the 16th century (redrawn from Tozzer, 1941).

syllabary, or 'grid of syllables,' is nearing completion (Montgomery, 2002). The first syllabary, considered a kind of Rosetta Stone for the region, was elicited from Yukatek Maya (the Maya of Yucatán) speakers by the Spanish friar Diego de Landa in the 16th century (Tozzer, 1941). This syllabary has helped several generations of scholars discover Mayan syllables and evidence for more phoneticism (Figure 8). Knorozov (1967), Kelley (1968), Lounsbury (1973), and others are usually credited with 'phonetic decipherment' of Mayan script, but phoneticism has a far longer history, going back to Brinton (1870), Thomas (1893), Beyer (1930), Whorf (1933), Thompson (1944), and others (Houston *et al.*, 2001). As is so often the case, Mayan decipherment was a slow process with many contributors, not a sudden breakthrough made by one individual.

In Mayan texts, logograms and syllables were often combined in the same glyph block in creative ways. For example, a main sign could be a logogram to which an affix could be attached to serve as a phonetic complement. We see this in Figure 9, where the syllable *ka* is prefixed to the logogram of a snake (*Kan*), the

Figure 9 Various logograms and phonetic complements can be combined to express the place name '*Kan*,' the ancient name for Calakmul. The fish and comb signs – both of which supply the sound *ka* – serve to reinforce the logograms for K'UHUL KAN AJAW, 'holy ruler of Calakmul' (adapted from Marcus, 1987).

Figure 10 We can paraphrase this Maya text (recorded on a wooden lintel in Temple I at Tikal, Guatemala, and drawn by K. Clahassey and J. Klausmeyer) as follows (labels written in all caps refer to logograms, while labels written in lowercase refer to phonetic elements.): 'From February 28 (the new year) we count forward 7 ''months'' and 18 days to August 5, the defeat of Fiery Claw, divine ruler of Kan (Calakmul).'

ancient name of Calakmul. To reduce ambiguity about the main sign, *Kan*, the phonetic complement *ka* was added to provide the initial sound. The *ka* prefix could be either a fish or a comb, and it was this interchangeability of signs that has been called "the principle of substitution" (Thompson, 1944).

The reading order of most Mayan texts with multiple columns is left to right, top to bottom, often by paired columns in which glyph A1 is read, then B1, then A2, B2, then A3, B3, and so on (Figure 10). Mayan sentences, like those of the Zapotec, were 'verb initial.' Sentences were either VS (verb + subject) or VOS (verb + object + subject). Hieroglyphic signs for verbs carried affixes to indicate whether the action was incomplete (ongoing) or complete. Unlike English, Mayan languages made a distinction between pronouns associated with *intransitive* verbs and pronouns associated with *transitive* verbs. Linguists designate these sets of pronouns 'A' and 'B' – *Set A* was affixed to the subjects of transitive verbs and to possessors of nouns; *Set B* marked the subjects of intransitive verbs and the objects of transitive verbs.

Third person singular possessive – her/his/its – was expressed as '*u*' in Mayan. This sound was used so often, in fact, that 8 to 10 separate signs were created to express it, and one of those appeared in Diego de Landa's 16th-century syllabary (Figure 8). Two examples of *u* as a 'possessor of nouns' include (1) *u-baak*, which could refer either to 'his bone' or 'his captive,' and (2) *u-muknal*, 'his tomb.' In front of a word beginning with a vowel, the Maya used '*y*' rather than '*u*.' For example, 'his spouse' would be *yatan* (*y* + *atan*) and 'his house' *yotot* (*y* + *otot*) (Figure 11).

Transitive completive verbs often carried the prefix *u* and the suffix *wi*, *aw*, or *wa*; intransitive completive verbs often took the suffix *hiy*, *yi*, or *iiy*. Some intransitive verbs were given 'positional' affixes, which referred to sitting, lying down, or other positions. For example, the verb 'seated in office' usually took a suffix such as *wan* or *waniy* (Figure 12A).

Special prefixes served as gender markers or agentive nouns. For males *aj* was used to indicate 'he' or 'he of' (*aj pits*, 'he, the ballplayer'; *aj mutul*, 'he of Mutul' [Tikal]). For females *ix* was used to indicate 'she' or 'she of' (*ix mutul*, 'she of Mutul'; *ix kan ajaw*, 'Lady of Kan' [Lady of Calakmul]). Some royal women also held the important title of *kaloomte'* (ruler) or *lak'in kaloomte'* (east ruler) (Figure 12B).

Maya hieroglyphic writing on stone fell into disuse after A.D. 909. However, both in the Maya region and elsewhere, hieroglyphic writing continued to be

Figure 11 The prefix *u* – his/her/its – is common in Maya writing; and, before a word that begins with a vowel, *y* is used (adapted from Marcus, 1992). (Labels written in all caps refer to logograms, while labels written in lowercase refer to phonetic elements.)

Figure 12 Examples of Maya writing that combine logograms and phonetic elements: (A) Was seated in office (adapted from Marcus, 1992); (B) Holy woman of Calakmul (adapted from Marcus, 1992). (Labels written in all caps refer to logograms, while labels written in lowercase refer to phonetic elements.)

painted in books or codices made of bark paper or deer hide sized with lime. Among those cultures relying on polychrome painted codices were the Mixtec and Aztec.

Mixtec Writing

Mixtec writing was a 'partial' system that served to label scenes. It provided the dates of events and the names of people and places, functioning much like the earlier Zapotec system. Mixtec writing relied heavily on logograms (signs standing for whole words), but there was also some use of phonetic elements, particularly in place names (Smith, 1973).

Between A.D. 1000 and 1600, a number of books painted by the Mixtec (codices Selden, Nuttall, Bodley, Colombino, and Becker) provide the histories and genealogies of Mixtec towns and their ruling dynasties. In these codices we see pictures of nobles, accompanied by short captions that supply their personal names. These names usually had two parts: (1) a name taken from the 260-day calendar, followed by (2) a nickname (e.g., 'Tiger Claw'), which distinguished that individual from others with the same calendar name.

Mixtec place signs could utilize phonetic elements. One well-known example is the sign for the town of Teozacoalco. Its Mixtec name, *Chiyo canu*, meant 'large platform.' Since the word 'large' was difficult to depict, the Mixtec used a homonym for *canu*, which also meant 'bend' or 'break.' Thus, *Chiyo canu* was depicted in painted books as a platform being bent by a small man (Figure 13A). Since Mixtec is a tonal language, one could use an easily depicted word that differed from a hard-to-depict one in tone only.

Mixtec scribes also drew upon idiomatic expressions that could be depicted. Well-known examples are (1) "there was a royal celebration of the mat" and "the royal vessel was presented to the noble," both of which referred to a royal wedding (Figure 13B); and (2) "to put an arrow into the lands of another," which referred to conquest (Figure 13C). Smith (1973) has shown that many pictorial conventions used in the codices reflected idioms and metaphors in the Mixtec language. Compared with Maya writing at its peak, Mixtec writing cannot be characterized as more than a restricted system of logographic signs, symbols, and pictorial conventions.

Aztec Writing

As in the case of the Mixtec, our principal sources of Aztec writing are painted codices, such as the *Matrícula de Tributos*, the *Tira de la Peregrinación*, and the *Borbonicus*. There are also stone monuments that were commissioned by Aztec rulers, such as the Stone of Tizoc and the Teocalli de la Guerra Sagrada, but the number and length of such inscriptions are

Figure 13 (A) The rebus principle is used to convey the Mixtec town *Chiyo canu*, which means both 'great platform' and 'bent platform.' Since it is easier to convey 'bent' than 'great,' the Mixtec used a man in the act of bending the platform to represent that town (redrawn from Marcus, 1992); (B) A Mixtec marriage could be conveyed by showing a bride facing a groom and/or by presenting him with a vessel of the beverage *pulque*. A lord named 4 Wind (at left) is married to a lady 5 Lizard (at right). This scene expresses the Mixtec expression for marriage, *nisiñe saha ya,* ''the royal vessel was placed before the nobleman'' (redrawn from Marcus, 1992); (C) One convention for conquest was to show a spear or arrow thrust into a hill, which corresponds to the Mixtec expression *chihi nduvua ñuhu ñaha*, ''to put an arrow into the lands of another'' (redrawn from Marcus, 1992).

limited by Maya standards (Dibble, 1971; Nicholson, 1973).

The *Matrícula de Tributos* deals with the tribute paid by each province incorporated into the Aztec Empire, but because this painted book was commissioned by the conquering Spaniards, it contains a mixture of pre-Hispanic and post-Hispanic conventions. Current evidence suggests that among all the Mesoamerican groups, only the Aztec used writing to keep province-by-province, commodity-by-commodity tribute records. The Aztec used logograms

Figure 14 Aztec signs for numbers and units of tribute, as painted in the 16th century A.D. in the Basin of Mexico (redrawn from Marcus, 1992).

for different quantities of goods, using a vigesimal system like all Mesoamericans. To indicate the number 1, they used a finger or dot; for 20, a flag; for 400, an upright feather; and for 8000, a bag or pouch. These numeric logograms were attached to pictures of goods in the Aztec tribute lists. For example, to indicate '402 blankets,' the Aztec scribe used two fingers plus a feather, attaching those signs to a blanket with the desired design (Figure 14).

Aztec writing relied heavily on pictograms. For example, a mat could stand for royal authority, a flower for sacrificial blood, and a burning temple for conquest. Proper nouns showed a limited use of phonograms and phoneticism. For example, the sign for water, *atl*, was used to reinforce the initial 'a' sound of the ruler's name Ahuitzotl and the town name Acolman. Other examples include the use of the sign for tooth, *tlan(tli)*, to reinforce the final sound, *tlan*, in the town name Mazatlán ('Place of the Deer'), and the sign for flag, *pan(tli)*, to reinforce the final syllable in the town name Tochpan ('Place of the Rabbit').

Synthesis and Conclusions

Writing in Mesoamerica seems to have emerged in an era of chiefly competition, when simple scenes and iconography proved insufficient to give the names of early leaders and the specific dates of early ritual and political events. If (as some believe) the precursors of writing are to be found in the iconography of roller stamps, we must look to the central highlands of Mexico, where those artifacts appeared earliest and

in greatest numbers. By 600 B.C. (uncalibrated), there were stone monuments with a few glyphs; and by 400 B.C., the Zapotec of Oaxaca were carving columns of pure text unaccompanied by scenes. Both Zapotec and Isthmian scripts preceded the emergence of the first states, but later, during the era of the Maya state, hieroglyphic writing achieved its greatest elaboration.

The next frontier for Mesoamerican epigraphers will be to resolve the controversy over Isthmian script and to analyze other undeciphered scripts, such as that seen at Kaminaljuyú in the Guatemala highlands, at Teotihuacán and Xochicalco in central Mexico, and in the Nuiñe region of Southern Puebla (Mexico).

Mesopotamian Cuneiform Script

G B Gragg, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Origins: Pre- and Protocuneiform

The earliest certain written records from Mesopotamia are tablelike notations of transactions and inventories, involving such language and language-related elements as graphic representations of numerals, and then, increasingly, proper names, and terms for natural kinds and artifacts, and descriptors for scenarios (i.e., verbs). Around 5000 of these administrative documents have been discovered in the southern Mesopotamian city of Uruk, dating roughly to the last centuries of the 4th millennium B.C.E. (around 3200–3000 B.C.E.), found in the archaeological strata referred to as Uruk IV and Uruk III. Records of this kind may or may not have developed out of earlier clay objects, known as tokens, supposedly used to represent collections of transaction-related realia (Schmandt-Besserat, 1992). Although doubts have sometimes been expressed in the literature about the language of the earliest texts, it is now generally accepted that they are in Sumerian, and indeed that the cuneiform writing system itself evolved in a Sumerian language context.

Sumerian Cuneiform

The signs in the earliest tablets are clearly pictographic in nature, as illustrated in Figure 1. However, considerations of speed of execution and adaptation to the abundantly available writing material (a damp, malleable clay surface, usually about palm size, subsequently sun-dried and hardened, rarely oven-baked) favored a rapid evolution toward simplification, linearization, and finally complete abstraction of sign shapes. By the middle of the 3rd millennium, in the pre-Sargonic period, the pictographic origins of almost all sign shapes had been effectively disguised. The 'speed writing' technique, which evolved under bureaucratic pressure to produce thousands upon thousands of administrative records, involved executing each linear constituent of a given sign in a single stroke by pressing the triangular head of a stylus into the malleable clay, making a wedge-shaped ('cuneiform,' from Latin *cuneus* 'wedge') impression, followed by a variable-length tail left by the impression of the straight edge of the stylus (see a typical example in Figure 2). Subsequently, when the occasional 'cuneiform' text was produced on a nonmalleable substance such as stone or metal, for monumental, dedicatory, or similar purposes, the shape occurring naturally from the interaction of stylus and clay was painstakingly reproduced in the more refractory medium.

Another dynamic at work in the development of Mesopotamian cuneiform had to do with the systematization of the sign inventory. The earliest 'texts' were largely listlike inventories of realia (think of a spreadsheet), and as such did not need to deal with a number of the complexities of complete representation in graphic media of natural language. The earliest pictographic stage had a large, and apparently growing, inventory of largely pictographic signs – at least 800, and probably more. As other text genres were added, it became necessary to represent not only a more extensive and abstract vocabulary, but also the myriad nominal suffixes and verbal prefixes and suffixes of Sumerian. Rather than accomplish this by continuing to add to the sign inventory, the latter, on the contrary, was streamlined and gradually reduced to about 600 signs, an inventory which then remained relatively stable for the remaining two-and-a-half millennia of cuneiform writing.

This streamlining was rendered possible by two processes. First, more than one logographic (= 'word') value could be assigned to a single sign. For example, the sign conventionally designated (from one of its most frequent values) 'AN,' which originally was a picture of a star, was assigned not only the word value (logographic value) *an* 'sky,' but also, by association, *dinger* 'god.' Other logographic values were assigned to combinations of signs: thus the sign 'KA,' a picture of a head with the mouth area emphasized, was assigned by the Sumerian scribes not only the logographic value *ka* 'mouth,' but also, by association, a number of other values, including *zú* 'tooth,' dug_4 'speak,' and

Mesopotamian Cuneiform Script

Origins: Pre- and Protocuneiform

The earliest certain written records from Mesopotamia are tablelike notations of transactions and inventories, involving such language and language-related elements as graphic representations of numerals, and then, increasingly, proper names, and terms for natural kinds and artifacts, and descriptors for scenarios (i.e., verbs). Around 5000 of these administrative documents have been discovered in the southern Mesopotamian city of Uruk, dating roughly to the last centuries of the 4th millennium B.C.E. (around 3200–3000 B.C.E.), found in the archaeological strata referred to as Uruk IV and Uruk III. Records of this kind may or may not have developed out of earlier clay objects, known as tokens, supposedly used to represent collections of transaction-related realia (Schmandt-Besserat, 1992). Although doubts have sometimes been expressed in the literature about the language of the earliest texts, it is now generally accepted that they are in Sumerian, and indeed that the cuneiform writing system itself evolved in a Sumerian language context.

Sumerian Cuneiform

The signs in the earliest tablets are clearly pictographic in nature, as illustrated in Figure 1. However, considerations of speed of execution and adaptation to the abundantly available writing material (a damp, malleable clay surface, usually about palm size, subsequently sun-dried and hardened, rarely oven-baked) favored a rapid evolution toward simplification, linearization, and finally complete abstraction of sign shapes. By the middle of the 3rd millennium, in the pre-Sargonic period, the pictographic origins of almost all sign shapes had been effectively disguised. The 'speed writing' technique, which evolved under bureaucratic pressure to produce thousands upon thousands of administrative records, involved executing each linear constituent of a given sign in a single stroke by pressing the triangular head of a stylus into the malleable clay, making a wedge-shaped ('cuneiform,' from Latin *cuneus* 'wedge') impression, followed by a variable-length tail left by the impression of the straight edge of the stylus (see a typical example in Figure 2). Subsequently, when the occasional 'cuneiform' text was produced on a nonmalleable substance such as stone or metal, for monumental, dedicatory, or similar purposes, the shape occurring naturally from the interaction of stylus and clay was painstakingly reproduced in the more refractory medium.

Another dynamic at work in the development of Mesopotamian cuneiform had to do with the systematization of the sign inventory. The earliest 'texts' were largely listlike inventories of realia (think of a spreadsheet), and as such did not need to deal with a number of the complexities of complete representation in graphic media of natural language. The earliest pictographic stage had a large, and apparently growing, inventory of largely pictographic signs – at least 800, and probably more. As other text genres were added, it became necessary to represent not only a more extensive and abstract vocabulary, but also the myriad nominal suffixes and verbal prefixes and suffixes of Sumerian. Rather than accomplish this by continuing to add to the sign inventory, the latter, on the contrary, was streamlined and gradually reduced to about 600 signs, an inventory which then remained relatively stable for the remaining two-and-a-half millennia of cuneiform writing.

This streamlining was rendered possible by two processes. First, more than one logographic (= 'word') value could be assigned to a single sign. For example, the sign conventionally designated (from one of its most frequent values) 'AN,' which originally was a picture of a star, was assigned not only the word value (logographic value) *an* 'sky,' but also, by association, *dinger* 'god.' Other logographic values were assigned to combinations of signs: thus the sign 'KA,' a picture of a head with the mouth area emphasized, was assigned by the Sumerian scribes not only the logographic value *ka* 'mouth,' but also, by association, a number of other values, including *zú* 'tooth,' dug_4 'speak,' and

Figure 1 Development of seven cuneiform signs from early 'pictographic' through 'archaic,' Old Babylonian, and Neo-Assyrian shapes (with permission of the Oriental Institute, University of Chicago).

inim 'word'; while the sign 'NINDA' = *ninda* 'food' combined with (in this case, written within) the 'KA' 'mouth' sign was assigned the value gu_7 'eat' (see Figure 1).

The most important streamlining step, however, was the re-interpretation of one (or more) of the logographic values of a sign as a purely phonological **syllabic** value, independent of its original association with a specific lexical item (to which it often had originally a pictographic link). The signs so adapted for the most part had a V, CV, or VC value, to a much smaller extent CVC. By this means the cuneiform writing system became a syllabary. A regular grid of syllabic values gradually emerged, covering, with some gaps and a certain amount of overlap, most possible combinations of a Sumerian consonant (the inventory as presently recognized is /p, b, t, d, k, g, h, s, z, š, m, n, ŋ, l, r, w, j/) preceded or followed by each of the four recoverable Sumerian vowels, /i, e, a, u/. Among the notable gaps, for example, is the absence of a consistent distinction for C*i* vs. C*e* signs for many consonants, particularly in the velar series. A more systematic gap is that in VC signs, no distinction is made between voiced and voiceless consonants: thus there exist distinct signs *ba* vs. *pa* and *ga* vs. *ka*, but only one sign *ab* = *ap* and *ag* = *ak*.

Cuneiform signs thus reinterpreted as syllabograms could be used to express lexical items, so that, for example, the logograms *ba* 'distribute' and *al* 'hoe' could be combined as syllabograms *ba-al* to render the word for 'dig' (presumably /bal/). For rendering lexical items, however, Sumerian made only sparing

Figure 2 Cuneiform administrative text (with permission of the Oriental Institute, University of Chicago).

use of this possibility, and preferred to represent lexical items by logographic values. But syllabograms were indispensable for rendering the often complex sequences of prefixes (for the verb) and suffixes (for the verb and noun) which characterized Sumerian morphology; and the accurate representation of this morphology was clearly felt to be more necessary as the cuneiform corpus became gradually extended beyond the original listlike economic and administrative texts to other genres of texts such as hymns, proverbs, and dedicatory and commemorative inscriptions. Thus the 'KA' sign discussed above could be used to represent the sequence of genitive suffix-*(a)k* followed by locative suffix -*a* as in:

é lugal-ak-a
house king-GEN-LOC
'in the house of the king,'

which would be written *é lugal-la-ka* (where also the syllabogram *la* is used to represent the [only graphically?] geminated final /l/ of the word for 'king' plus the initial /a/ of the genitive suffix).

At first such syllabic values were introduced only selectively, to make explicit some of the most important grammatical features. Indeed, in the earliest texts, the order of the logographically used signs themselves within the ruled cases which divided a tablet was somewhat arbitrary. The written text, especially for traditional religious or literary compositions, was thus functioning as something of an *aide-mémoire* for a text with which the 'reader' was supposed to be fairly familiar. The story of the development of Sumerian cuneiform is from one point of view that of a gradually more complete written expression of a Sumerian utterance. It is important to keep in mind,

with respect to our knowledge of Sumerian grammar, that the problem of full representation in principle of a Sumerian sentence was dealt with by Mesopotamian scribes only gradually, after written versions of some texts had been in existence for several centuries; and that the fullest representation of all nominal and verbal affixes was only approached when Sumerian had already ceased to be the native language of the scribal classes.

A final use of cuneiform signs is as semantic determiners, indicating that the following (or in some cases preceding) noun belongs to a certain class. This was especially widespread among proper nouns, with certain cuneiform signs, in addition to whatever logographic or syllabic function they might have, serving as indicators that the following sign or sequence of signs was to be interpreted as a male personal name, a female personal name, a divine name, city name, country name, river name, etc. Determinatives were also used for certain classes of common nouns: plants, trees and wooden objects, pots, etc. Thus the sign whose logographic value was *ŋiš* 'tree' could also be a determinative for trees or wooden artifacts (and later could also function as an Akkadian syllabogram *-iṣ/z/s*, from the Akkadian logographic value *iṣum* 'tree, wood').

The particular complexity of the Sumerian cuneiform writing system stems from this combination of possible sign interpretations. Sumerian scribes maintained the use of logograms up to the end, and never took the step of transforming cuneiform into a purely syllabic writing system. Cuneiform remained always a mixed logographic/syllabic system, with a comparatively restricted inventory of signs (ca. 600), in which most could have one or more logographic readings; many signs, in addition, could have one (less often several) syllabic reading, and some a reading as a determinative. When this complexity (frequently referred to as polysemy) is combined with an apparently high degree of homophony (almost certainly only apparent, owing to our imperfect grasp of the phonological distinctions functioning in Sumerian), the incredulity with which early 19th-century decipherments of cuneiform were met is understandable. In this context it should be noted that the accents and subscripts assigned by modern scholarship to logographic and syllabic values have a purely diacritic function, to distinguish the transcriptions of distinct signs which would be otherwise homophonous. Thus the distinct signs presumed to have the logographic (and in some cases syllabographic) value, as near as we can determine, /e/ have been assigned transcription values e, é (or e_2), è (or e_3), e_4, e_5 ... more or less in the order in which the values were discovered.

Extension of Sumerian Cuneiform to Other Languages

From the Uruk period onwards, Sumerian culture and cultural institutions enjoyed enormous prestige throughout ancient western Asia, and were adopted and adapted to varying degrees by neighboring states and ethnic groups, but in particular by the ethnic group who gradually displaced the Sumerians in their Mesopotamian homeland – the Akkadians (and their close Semitic cousins to the west, the Eblaites).

The process of gradually reinterpreting and adapting the Sumerian cuneiform writing system to the needs of Akkadian started early in the 3rd millennium, as the necessity arose to render Akkadian proper names in Sumerian contexts. With the rise of powerful Akkadian city-states in northern Mesopotamia around 2500 B.C.E. (followed shortly by the city-state of the closely related Eblaites in northern Syria), it became necessary to use the logographic-syllabic system to render a whole repertory of Akkadian texts: monumental and administrative texts, letters, even religious and literary texts. In this adaptation, as in other subsequent ones, there was a considerable scaling down of logographic values, but never a complete elimination – the logograms used in the texts were written as though they were Sumerian, but presumably read in Akkadian. Moreover, since Sumerian literary and scholastic texts (word lists, bilingual lexical texts) continued to be used in the scribal schools, additional Sumerian logographic values were always accessible, and could be introduced at different periods or into certain genres of text, as was the case massively in certain abstruse and highly specialized genres such as medical and magical texts.

The most distinctive part of the adaptation was in the syllabary. While a few new Akkadian syllabic values were created from Akkadian equivalents of Sumerian logograms (thus: Sumerian *á* 'arm' = Akkadian *idu*, whence was derived a new Akkadian syllabic value *id* for the sign 'Á'; note also the example of *ŋiš* given above). For the most part, however, Akkadian syllabograms were created by the mapping of Sumerian syllabic values onto Akkadian near equivalents. This mapping was not entirely self-evident, even where the same or similar distinctions existed in Sumerian and Akkadian, e.g., voiced vs. voiceless stops; and it became particularly problematic for distinctions (e.g., an 'emphatic,' presumably glottalized) or segments (some pharyngeal and sibilant consonants) which did not exist in Sumerian. After an initial period in which only place of articulation was distinguished (thus, 'DA' has syllabic values *ta*, *da*, *ṭa*), a gradual, but never complete separation of values was achieved with a core syllabary usually containing about 90

signs, whose precise makeup varied from period to period and place to place. It has been estimated that for most periods of Akkadian, for most common text genres the syllabary plus the usual determinatives and logograms yields a grand total of about 200 signs in common use.

Following in the wake of Akkadian, and in one way or another influenced by the prestige and geographic reach of Mesopotamian culture, a number of other languages of ancient western Asia systematically adapted the cuneiform writing system and created more or less sizable text corpora. Principal among these are the language isolates Elamite, Hurrian, and Urartian (closely related to each other), plus the well-known Indo-European language Hittite. Common to all these adaptations is the streamlining and greater systematization of the syllabary, plus a considerable reduction in the number of logograms and determinatives.

By the middle of the 1st millennium B.C.E., cuneiform began to be seriously challenged by simpler alphabetic writing systems using other, lighter, but more expensive and more perishable materials. In Mesopotamia, Akkadian itself was gradually replaced as the spoken and then as the administrative language by Aramaic, words and phrases of which were occasionally daubed onto tablets, but which had found its means of written expression outside cuneiform. Continuing a shadow existence for certain traditional administrative and scholarly purposes, the last cuneiform tablets seem to have been drawn up as late as the 1st century C.E.

Metalanguage versus Object Language

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Human languages are the objects studied in linguistics. For that reason, the language under investigation is known as the object language. The language that a linguist uses to describe and analyze the object language is called the metalanguage. The basic requirement for a metalanguage is that it satisfactorily communicates the form, structure, and meaning of item e_{OL} – that is, any expression in the object language, whether it is a word, a phrase, or a sentence – in terms of an expression 'e_M' in the metalanguage. This short article focuses on semantic metalanguages.

Ideally, a metalanguage is a formal language, as in (2); (1) is informal.

(1) *dog* means 'canine animal'

(2) $\forall x[\mathrm{D}(x) \leftrightarrow \lambda[\mathrm{A}(y) \wedge \mathrm{C}(y)](x)]$

Dog is e_{OL} and 'canine animal' is 'e_M'; note the typographical differentiation. Example (2) makes recourse to natural language vocabulary because the D, A, and C symbolize *dog*, *animal*, and *canine*; (2) can be read 'Everything that is a dog is a member of the set of individuals that are both animal and

signs, whose precise makeup varied from period to period and place to place. It has been estimated that for most periods of Akkadian, for most common text genres the syllabary plus the usual determinatives and logograms yields a grand total of about 200 signs in common use.

Following in the wake of Akkadian, and in one way or another influenced by the prestige and geographic reach of Mesopotamian culture, a number of other languages of ancient western Asia systematically adapted the cuneiform writing system and created more or less sizable text corpora. Metalanguage versus Object Language

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Human languages are the objects studied in linguistics. For that reason, the language under investigation is known as the object language. The language that a linguist uses to describe and analyze the object language is called the metalanguage. The basic requirement for a metalanguage is that it satisfactorily communicates the form, structure, and meaning of item e_{OL} – that is, any expression in the object language, whether it is a word, a phrase, or a sentence – in terms of an expression 'e_M' in the metalanguage. This short article focuses on semantic metalanguages.

Ideally, a metalanguage is a formal language, as in (2); (1) is informal.

(1) *dog* means 'canine animal'

(2) $\forall x[\mathrm{D}(x) \leftrightarrow \lambda[\mathrm{A}(y) \wedge \mathrm{C}(y)](x)]$

Dog is e_{OL} and 'canine animal' is 'e_M'; note the typographical differentiation. Example (2) makes recourse to natural language vocabulary because the D, A, and C symbolize *dog*, *animal*, and *canine*; (2) can be read 'Everything that is a dog is a member of the set of individuals that are both animal and

canine'. Strictly, a formal language has a fully defined vocabulary and syntax. Ideally, the vocabulary is a specified set of symbols whose forms and correlated meanings are fully defined, all possible combinations of vocabulary items in the metalanguage are generated from fully specified syntactic axioms and rules of syntax, and the meanings of syntactically well-formed structures are fully specified by semantic axioms and rules for the metalanguage.

A metalanguage is, in effect, a translation of the object language (Carnap, 1937: 228); so, defining a formal metalanguage for natural language semantics requires that it have the same expressive power as a natural language. In order for the metalanguage to be understood and used by human beings, it must be communicable and, hence, translate into a natural language. If you understand neither Polish nor Swahili, there is little point in my using Swahili as a metalanguage for the semantic analysis of Polish (or vice versa); for example, my saying that *to jest pies* means 'ni mbwa' will not help you at all. Using English as a metalanguage, I would say *to jest pies* means 'it's a dog'; using English as a meta-metalanguage, I would say *to jest pies* means 'ni mbwa' (in Swahili), which means 'it's a dog.'

The advantages of a formal metalanguage are the explicit definition of primitives and standards of rigor and exactitude that tend to be ignored when using an informal metalanguage. The proper formalization of the metalanguage permits proofs of particular conclusions about semantic structure and so prevents mistaken conclusions deriving from faulty assumptions and/or inference procedures. However, none of these advantages of a formal system is necessarily unobtainable using an informal system such as a natural language metalanguage for semantics. Given two metalanguages with the same descriptive and explanatory capacities, the only way to choose between them is to be guided by gut feeling: favor the one you are happier with. A metalanguage is the product of an analyst's mind; the analyst not being God, every metalanguage is limited by the beliefs, perspectives, and purposes of its creator.

Metaphor and Conceptual Blending

S Coulson, University of California, San Diego, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

'Metaphor' was defined by Aristotle (*Poetics* XXI, 1457b) as "... giving the thing a name belonging to something else, the transference being ... on the grounds of analogy." More succinctly, Quintilian (VIII, VI, 1) defined metaphor as "the artistic alteration of a word or phrase from its proper meaning to another." Traditionally, then, metaphor is defined as a 'trope,' a nonstandard meaning used for its literary effect. On this view, any cognitive significance attributed to metaphorical phenomena is of a negative character. Hobbes (*Leviathan*), for example, argued that metaphors are "... *ignes fatui*; and reasoning upon them is wandering amongst innumerable absurdities ...."

In contrast to the view of metaphor as a literary curiosity, cognitive semanticists such as Lakoff and Johnson (1980), Sweetser (1990), and Turner (1991) have argued that metaphor is a pervasive phenomenon in everyday language and, moreover, that it represents the output of a cognitive process by which we understand one domain in terms of another (*see* **Cognitive Semantics**). Cognitive linguists define metaphor as reference to one domain with vocabulary more commonly associated with another domain. Thus construed, metaphoric language is the manifestation of conceptual structure organized by a 'crossdomain mapping': a systematic set of correspondences between two domains, or conceptual categories, that results from importing

canine'. Strictly, a formal language has a fully defined vocabulary and syntax. Ideally, the vocabulary is a specified set of symbols whose forms and correlated meanings are fully defined, all possible combinations of vocabulary items in the metalanguage are generated from fully specified syntactic axioms and rules of syntax, and the meanings of syntactically well-formed structures are fully specified by semantic axioms and rules for the metalanguage.

A metalanguage is, in effect, a translation of the object language (Carnap, 1937: 228); so, defining a formal metalanguage for natural language semantics requires that it have the same expressive power as a natural language. 'Metaphor' was defined by Aristotle (*Poetics* XXI, 1457b) as "... giving the thing a name belonging to something else, the transference being ... on the grounds of analogy." More succinctly, Quintilian (VIII, VI, 1) defined metaphor as "the artistic alteration of a word or phrase from its proper meaning to another." Traditionally, then, metaphor is defined as a 'trope,' a nonstandard meaning used for its literary effect. On this view, any cognitive significance attributed to metaphorical phenomena is of a negative character. Hobbes (*Leviathan*), for example, argued that metaphors are "... *ignes fatui*; and reasoning upon them is wandering amongst innumerable absurdities ...."

In contrast to the view of metaphor as a literary curiosity, cognitive semanticists such as Lakoff and Johnson (1980), Sweetser (1990), and Turner (1991) have argued that metaphor is a pervasive phenomenon in everyday language and, moreover, that it represents the output of a cognitive process by which we understand one domain in terms of another (*see* **Cognitive Semantics**). Cognitive linguists define metaphor as reference to one domain with vocabulary more commonly associated with another domain. Thus construed, metaphoric language is the manifestation of conceptual structure organized by a 'crossdomain mapping': a systematic set of correspondences between two domains, or conceptual categories, that results from importing

frames or cognitive models from one domain to another.

Conceptual Metaphor Theory

In 'conceptual metaphor theory,' metaphorical expressions are the linguistic manifestation of underlying conceptual knowledge. Whereas traditional approaches have tended to consider metaphorical uses of words and phrases on a case-by-case basis, cognitive linguists have pointed to patterns in the metaphorical uses of word meanings. For example, in (1) through (4) we see a number of examples that employ words whose literal meaning concerns the domain of vision, used metaphorically to characterize the domain of understanding. In such cases, the real topic of discussion (e.g., understanding) is known as the 'topic' or 'target' domain, while the domain characteristically associated with the vocabulary (e.g., seeing) is known as the 'vehicle' or 'source' domain.

(1) The truth is *clear*.

(2) He was *blinded* by love.

(3) His writing is *opaque*.

(4) I *see* what you mean.

In these and many such examples of this metaphoric mapping, the relationship between the domains is systematic: if seeing corresponds to understanding, then not seeing corresponds to not understanding, faulty vision corresponds to faulty understanding, and so forth. In conceptual metaphor theory, the systematic nature of the relationships between domains in the metaphor results from mapping cognitive models from one domain onto counterparts in the other. This results in a transfer of images and vocabulary from the source domain onto the target. Moreover, it also involves the projection of inferential structure so that inferences from the source domain can be translated into parallel inferences and counterparts in the target. For instance, in the SEEING domain, if someone is 'blinded' he will be unable to see. Analogously, in the KNOWING domain, if someone is 'blinded' he will be unable to apprehend certain sorts of information. For this reason, metaphor is considered a conceptual phenomenon, rather than merely a lexical one (*see* **Meaning: Cognitive Dependency of Lexical Meaning**).

Viewing metaphorical language as a manifestation of the conceptual system explains why the correspondences between elements and relations in the two domains of a metaphor are systematic rather than random. Cognitive linguists argue that the systematicity in the usage of source and target domain terminology derives from the fact that some of the logic of the source domain has been imported into the target in a way that maintains the mappings from one to the other. Consequently, there are parallels between the source and target domains, both in word meanings and in the inferences that one might draw from sentences that use those word meanings. Although the objective features of the two domains in a metaphor are often quite different, the two domains can be seen as sharing abstract similarities.

Analyses of conceptual metaphors are typically stated in terms of the domains that are associated by the metaphor. The domain of vision, for instance, is metaphorically linked with the domain of knowledge and understanding. Consequently, these utterances are said to be instances of the KNOWING IS SEEING metaphor. Alternatively, metaphors can be described in terms of the high-level mapping between the two domains, as in Seeing → Knowing (Table 1). The latter notation is especially useful when the analyst wants to outline the correspondences between the two domains.

Conceptual metaphors such as KNOWING IS SEEING make up a pervasive repertoire of patterns in language and thought. The many expressions we can remember or create that conform to the pattern have been taken as evidence that, just as the metaphoric meanings of many of these words are conventional, so too are the metaphoric mappings. Consequently, a lexical analysis of metaphor is not complete unless it refers to the underlying mapping patterns.

The idea that knowledge of metaphoric mappings constitutes part of the linguistic competence of the speaker is supported by the use of conceptual metaphors in novel, poetic language (Lakoff and Turner, 1989). For example, in *To the lighthouse*, one of Virginia Woolf's characters describes moments of insight as "illuminations, matches struck unexpectedly in the dark." Although many of the linguistic expressions in this excerpt are creative, the conceptual mappings conform to the pattern in the KNOWING IS SEEING metaphor. Just as a match affords the possibility of seeing one's surroundings for a brief period of time, a moment of insight allows one to understand something for a brief moment of time. The seer in the match scenario corresponds to the knower, and

Table 1 Example of domain mapping

Seeing		*Knowing*
Seer	→	Knower
Thing seen	→	Topic of understanding
Quality of vision	→	Quality of understanding
Visual ability	→	Intelligence

the quality of vision corresponds to the quality of understanding.

Higher-Level Mappings

In addition to KNOWING IS SEEING, cognitive linguists have identified a large number of conventionalized metaphors, such as DESIRE IS HUNGER (*sex-starved*, *sexual appetite*), HOPE IS LIGHT (*dim hopes*, *ray of hope*), or LOVE IS A JOURNEY (*we've come a long way together, their marriage is going off-track, we're just spinning our wheels*) (see Lakoff and Johnson, 1980, 1999). That is, there are many expressions about desire, hope, and love that systematically exploit vocabulary from the domains of hunger, light, and journeys, respectively. As noted earlier, the systematicity derives from the fact that the mappings between elements in the source and the target domains are typically constant from expression to expression, and that many source domain inferences map onto analogous target domain inferences.

Moreover, many conventionalized metaphors such as LOVE IS A JOURNEY can themselves be seen as instantiations of more general crossdomain mappings. LOVE IS A JOURNEY, along with A CAREER IS A JOURNEY and even LIFE IS A JOURNEY, are all instantiations of a more general mapping between long-term purposeful activities and progress along a path. Indeed, the latter is part of a very abstract mapping scheme known as the 'event structure metaphor' (Lakoff, 1993; Lakoff and Johnson, 1999). As outlined by Lakoff (1993), the event structure metaphor includes the mappings outlined as follows.

States	→	Locations
Changes	→	Movements
Causes	→	Forces
Actions	→	Intentional movements
Purposes	→	Destinations
Means	→	Paths
Problems	→	Impediments to motion

Particular metaphoric expressions such as *dead-end relationship* can thus be seen as motivated by metaphoric mappings at multiple levels of abstraction (LOVE IS A JOURNEY, LONG-TERM PURPOSEFUL ACTIVITIES ARE JOURNEYS, and the event structure metaphor).

Primary Metaphor and Experiential Grounding

One important claim in conceptual metaphor theory is that 'primary metaphors' are grounded in correlations in experience. For example, the metaphorical mapping between quantity and height (MORE IS UP) is thought to be motivated by correlations between the number of objects in a pile and its height, or the amount of liquid in a glass and the height of the fluid level. In traditional accounts dating back to Aristotle, metaphors were based on similarities between the two domains invoked in the metaphor. By contrast, Lakoff and Johnson (1980) highlighted the existence of a large number of metaphorical expressions, such as *big idea,* whose two domains have no inherent similarities, arguing instead that such metaphors are experientially motivated.

The experiential motivation of metaphors is consistent with the fact that the mapping between the domains and entities in a primary metaphor is directional. For instance, although the conceptual metaphor KNOWING IS SEEING allows us to utter an expression such as *I don't see what you're saying* to indicate the existence of a comprehension problem, it does not license *I don't understand your face* to indicate a problem with visual acuity. Directionality is thought to reflect the underlying cognitive operations in metaphor, in which an experientially basic source domain is exploited to reason about a more abstract target domain. Indeed, many entrenched metaphors involve the use of a concrete source domain to discuss an abstract target. For example, importance is expressed in terms of size (as in *big idea* or *small problem*), similarity is construed as physical proximity (as in *close* versus *disparate* philosophical *positions*), and difficulties are discussed in terms of burdens (as in *heavy responsibilities*).

Primary metaphors originate in *primary scenes* in which critical aspects of the source and target domains cooccur with one another. For example, the KNOWING IS SEEING metaphor is thought to be motivated by contexts in which visual experience brings about understanding. In fact, corpus research shows that child-directed speech contains many utterances in which both the perceptual and the cognitive meaning of *see* are simultaneously present as in (5) (Johnson, 1999).

(5) Oh, I see what you wanted.

In fact, children produce many such utterances themselves, prompting the suggestion that the meaning of words such as *see* evidences 'conflation,' as the word refers simultaneously to the visual and the cognitive experience. Learning the metaphorical meaning is not a matter of generalizing from a concrete meaning to an abstract one, but rather requires 'deconflation,' in which the child gradually dissociates and distinguishes between the two domains in the metaphor (Johnson, 1999).

Primary metaphors such as KNOWING IS SEEING are directly grounded in experience, while other metaphors are only indirectly grounded. For example, the THEORIES ARE BUILDINGS metaphor is supported by examples like (6) to (8) from Grady

(1997), in which theories are discussed with verbiage that might appropriately be applied to buildings.

(6) You have failed to buttress your arguments with sufficient facts.

(7) Recent discoveries have shaken the theory to its foundations.

(8) Their theory collapsed under the weight of scrutiny.

However, it is unlikely that many people have correlated experiences of theories and buildings. Moreover, many experientially basic aspects of our concepts of buildings are not exploited in this metaphor, as in (9) and (10) (Grady and Johnson, 2002).

(9) This theory has no windows.

(10) I examined the walls of his theory.

Instances in which source domain language (in this case pertaining to buildings) has no target domain interpretation reveal 'metaphorical gaps.' Primary metaphors, however, do not evidence these gaps, as virtually any word that is meaningful in the source domain can be metaphorically interpreted in the target domain (Grady, 1999). Consequently, Grady (1997) suggested that the THEORIES ARE BUILDINGS mappings that underlie (6) through (8) arose from a combination of two primary metaphors: ORGANIZATION IS PHYSICAL STRUCTURE and PERSISTING IS REMAINING ERECT. Unlike the proposed mapping between theories and buildings, experiential grounding of a mapping between persistence and remaining upright is quite plausible (Grady, 1999).

Conceptual Blending Theory

Much of the linguistic data accounted for by conceptual metaphor theory can also be analyzed in terms of 'conceptual blending theory' (Fauconnier and Turner, 2002). An elaboration of 'mental space theory' (described later), the conceptual blending framework (also known as 'conceptual integration' and 'blending theory') assumes many of the same claims as conceptual metaphor theory, such as the idea that metaphor is a conceptual as well as a linguistic phenomenon and that it involves the systematic projection of language, imagery, and inferential structure between domains. However, in contrast to the emphasis on conventional metaphors in conceptual metaphor theory, conceptual blending theory is intended to capture spontaneous, online processes that can yield short-lived and novel conceptualizations. Furthermore, blending theory reveals connections between the cognitive underpinnings of metaphor and a variety of other linguistic phenomena handled by mental space theory.

Mental Space Theory

Mental space theory (Fauconnier, 1994) is a theory of referential structure, a level of conceptual organization between the situation being described and the linguistic structures that describe it (Langacker, 1993). Although motivated by linguistic data, mental spaces are not specifically linguistic in nature and reflect the operation of more general cognitive processes. In this framework, words do not refer directly to entities in the world. Rather, linguistic cues prompt speakers to set up elements in a referential structure that may or may not refer to objects in the world. Created to solve semantic problems created by referential opacity (*see also* **Factivity**) and indirect reference, mental spaces can be thought of as temporary containers for relevant information about a particular domain.

A mental space contains a partial representation of the entities and relations of a particular scenario as perceived, imagined, remembered, or otherwise understood by a speaker. This representation typically includes elements to represent each of the discourse entities, and simple frames to represent the relationships that exist between them. Mental space theory deals with many philosophical problems of meaning by employing multiple spaces to represent a single sentence. Although different spaces can contain disparate information about the same elements, each individual space is internally coherent, and together they function to represent all of the relevant information. In contrast to traditional approaches to meaning construction, the bulk of the cognitive work involves tracking the mappings between spaces rather than the derivation of a logical representation of sentence meaning.

(11) Orlando Bloom is the new James Bond.

(12) Iraq is the new Vietnam, as protests return to the airwaves.

(13) The new James Bond wears jewelry everywhere he goes.

In the context of a newspaper article about the signing of British actor Orlando Bloom to play the character James Bond in an upcoming spy movie, example (11) prompts the construction of two mental spaces, one for reality and one for the movie. Element *a* represents Orlando Bloom in the reality space, while element *a'* represents James Bond in the movie space. An 'identity' mapping between *a* and *a'*

represents the fact that in this context *a* and *a'* are the same person, even though Orlando Bloom the actor may not share all of his character James Bond's qualities.

Reality		*Movie*
a	→	a'
Bloom (a)		Bond (a')

In the context of an article about the increasing involvement of musicians in antiwar protests, (12) prompts the construction of two mental spaces: one for 2004 and one for 1970. Element *w* represents the American war with Iraq in the 2004 space, whereas element *w'* represents the American war with North Vietnam in the 1970 space. The link between these two elements is not identity, but rather **analogy.** Similarly, there is an analogy link between the contextually evoked protests in the 1970 space (*p'*) and the explicitly evoked protests in the 2004 space (*p*).

2004		*1970*
w	→	w'
p	→	p'
Location (w, Iraq)		Location (w', Vietnam)

Once elements in different mental spaces are linked by a mapping, it is possible to refer to an element in one space by using language more appropriate for the other space. For example, one might utter (13) to convey Orlando Bloom's penchant for wearing necklaces. As in (11), (13) would involve the construction of two mental spaces: one for reality and one for the movie. Element *b* stands for Bloom in reality space, whereas *b'* stands for Bond in movie space, and (given that wearing jewelry is unlikely for the very macho James Bond character) the predicate wears-jewelry pertains to *b* and not *b'*. Thus, in (13), the speaker refers to *b* (Bloom), only indirectly by naming its counterpart *b'* (Bond). In mental space theory, the possibility of using a term from one space to refer to a linked element in another domain is known as the 'access principle.'

Reality		*Movie*
b	→	b'
Bloom (b)		Bond (b')
Wears-Jewelry (b)		

The access principle is in fact central to the account of metaphor in mental space theory.

(14) Paris is the heart of France.

(15) The heart of France is under attack.

On Fauconnier's (1994) account, a metaphor such as (14) is handled by setting up two mental spaces: one for the source domain (anatomy) and one for the target (geography).

Anatomy		*Geography*
Heart	→	Paris
Body	→	France

The *heart* is linked to *Paris*, and the *body* is linked to *France* by analogy mappings. Once these spaces are linked, one can refer to Paris as *the heart of France,* as in (15). Moreover, as in conceptual metaphor theory, cognitive models that detail the importance of the heart to sustaining the body are cognitively accessible to the target domain and can be mapped onto target space counterparts.

Conceptual Blending and Metaphor

Fauconnier and Turner (1998) suggested that metaphoric mappings were one manifestation of a more general integration process that crucially involved the construction of blended mental spaces. 'Blended spaces' are mental spaces that are built up online to incorporate information from different frames, as well as local contextual information. Central to conceptual blending theory is the notion of the 'conceptual integration network,' an array of mental spaces in which the processes of conceptual blending unfold (Fauconnier and Turner, 1998). These networks consist of two or more input spaces structured by information from discrete cognitive domains, a generic space that contains structure common to the inputs, and a blended space that contains selected aspects of structure from each input space along with any emergent structure that arises in the course of comprehension. Blending involves the establishment of partial mappings between cognitive models in different spaces in the network and the projection of conceptual structure from space to space.

One motivation for blending theory is the observation that metaphoric expressions often have implications that do not appear to originate in either the source or the target domain. For example, although neither butchers nor surgeons are customarily considered incompetent, a surgeon metaphorically described by his or her colleagues as a *butcher* does not have a good reputation. In blending theory, appreciating this metaphor involves establishing mappings between elements and relations in the source input of butchery and the target input of surgery. As in conceptual metaphor theory, there is a mapping between surgeon and butcher, patient and dead animal, as well as scalpel and cleaver.

However, blending theory also posits the construction of a blended space in which structures from each of these inputs can be integrated. In this example, the blended space inherits the goals of the surgeon and the means and manner of the butcher (Grady *et al.*, 1999). The inference that the surgeon is incompetent

Table 2 Example of conceptual integration network

Surgeon Input space	*Blended Space*	*Butcher Input space*	*Generic Space*
Surgeon	S/B	Butcher	Agent
Patient	P/A	Animal	Patient
Scalpel	S/C	Cleaver	Cutting instrument
Goal: Heal patient	*Goal:* Heal patient	*Goal:* Kill animal	
Means: Precise cuts	*Means:* Slashing cuts	*Means:* Slashing cuts	
	Emergent inference: Incompetent (S/B)		

arises when these structures are integrated to create a hypothetical agent with both characteristics. Behavior that is perfectly appropriate for a butcher whose goal is to slaughter an animal is appalling for the surgeon operating on a live human being. Table 2 shows the conceptual integration network for *That surgeon is a butcher*. The fact that the inference of incompetence does not originate in the source domain of butchery is further suggested by the existence of other metaphoric uses of *butcher* – such as describing a military official as *the butcher of Srebenica* – that recruit structure and imagery from the butchery domain but do not connote incompetence. Differences in the implications of the butcher metaphor in the domains of medicine and the military highlight the need for an account of their underlying conceptual origin.

Blending can also be used to explain how the target domain influences the meaning of metaphoric expressions. For example, the metaphoric idiom *digging your own grave* is used to imply that someone is unwittingly contributing to their own failure (*see* **Idioms**). While this metaphor depends on conventional metaphoric mappings between death and failure, the meaning of the metaphor in the target domain does not seem to result from a straightforward projection from the source domain of grave digging. If the target domain concerns a case where one's ill-advised stock purchases lead to financial ruin, the digger maps onto the purchaser, the digging maps onto the purchasing, and the digger's death maps onto the purchaser's financial ruin. However, note that in the realistic domain of grave-digging, there is no causal relationship between digging and the grave-digger's death. The blended space thus invokes its imagery from the source input space but obtains its causal structure from the target input (Coulson, 2001; Fauconnier and Turner, 2002).

Furthermore, unlike metaphor theory, which attempts to explain generalizations in metaphoric expressions via the conceptual mappings that motivate them, conceptual blending theory attempts to explain meaning construction operations that underlie particular metaphoric expressions. Consequently, blending theory can address the meaning construction in metaphoric expressions that do not employ conventionalized mapping schemes. For example, the italicized portion of this excerpt from an interview with philosopher Daniel Dennet involves a metaphorical blend: "There's not a thing that's magical about a computer. *One of the most brilliant things about a computer is that there's nothing up its sleeve*" (*Edge 94*, November 19, 2001). The input domains here are *computers* and *magicians*, and the blend involves a hybrid model in which the computer is a magician. However, the connection between these two domains arises purely from the cotext of this example, as there is no conventional COMPUTERS ARE MAGICIANS mapping in English.

Blending also can be used to explain how a number of different kinds of mappings can be combined to explain the meaning of a particular example such as (16) (from Grady *et al.*, 1999).

(16) With Trent Lott as the Senate Majority Leader, and Gingrich at the helm in the House, the list to the Right could destabilize the entire Ship of State.

This example involves an elaboration of the conventional Nation-as-Ship metaphor, in which the Nation's policies correspond to the ship's course, leadership corresponds to steering the ship, and policy failures correspond to deviations from the ship's course. The Nation-as-Ship metaphor is itself structured by the more abstract event structure metaphor. The source input is the domain of Ships, which projects an image of a ship on the water, as well as the concept of the helm, to the blended space. The target input is the domain of American politics, which projects particular elements, including Trent Lott and Gingrich, to the blend, where they are integrated with the sailing scenario.

Example (16) describes the ship listing to the right. However, in the realistic domain of ships, neither the presence of one individual (Trent Lott) nor the beliefs of the helmsman are likely to cause the ship to list. The logic of this metaphoric utterance comes not from the source input but rather the target input in which the Senate Majority Leader and the Speaker of the House can affect national policies and the overall political orientation of government. Furthermore, the standard association between conservatism and the right as against liberalism and the left is clearly

not based on the ship model, as it is frequently encountered in other contexts. However, because the scenario in the blend involves spatial motion, the literal notion of rightward movement is integrated with the other structure in the blend to yield a cognitive model of a ship piloted by Newt Gingrich that lists to the right.

Consequently, Fauconnier and Turner (2002) proposed that metaphoric utterances are mentally represented in networks of mental spaces known as 'integration networks.' As noted earlier, conceptual integration networks are comprised of four mental spaces. The source and target domain each structure one input space; the generic space represents abstract commonalities in the inputs; and the blended space inherits structure from its inputs as well as containing emergent structure of its own. Rather than emphasizing the extent to which metaphorical utterances instantiate entrenched mappings between source and target domains, conceptual integration networks only represent those cognitive models that are particularly relevant to the mapping supported by the utterance. While mappings in the integration network require knowledge of conceptual metaphors, such as KNOWING IS SEEING, blending theory is best suited for representing the joint influence of input domains and the origin of emergent inferences in particular metaphoric utterances.

Metaphor, Conceptual Blending, and Linguistic Theory

In part because of its origin in mental space theory, conceptual blending theory suggests that the meaning construction operations that underlie metaphoric meanings are but a subset of those involved in other sorts of indirect reference. By treating all sorts of mappings as formally identical, it is possible to understand the transfer of structure in metaphor as being fundamentally similar to the transfer of structure in nonmetaphorical instances. Thus, regardless of whether or not the information being combined originates in different domains, the integrative operations can be understood as requiring the construction of mappings between partial structures that originate in different mental spaces.

This formal identity allows for the unification of the treatment of metaphor – which principally recruits analogy mappings – with the treatment of 'counterfactuals' and 'conditionals,' conceptual blends that often recruit identity mappings. A number of researchers working within the framework of conceptual blending have addressed its implications for counterfactuals (e.g., Coulson, 2000; Fauconnier, 1997; Oakley, 1998) (*see* **Counterfactuals**). Similarly, the formal treatment of all sorts of mappings is useful in explaining the variety of complex combinations coded for by modified noun phrases. For example, blending theory has been used to explore issues of noun modification in seemingly simple cases like *red pencil* (Sweetser, 2000), more exotic cases like *land yacht* and *dolphin-safe tuna* (Turner and Fauconnier, 1995), and privative constructions such as *alleged affair* and *fake gun* (Coulson and Fauconnier, 1996) (*see* **Compositionality: Semantic Aspects**).

The most obvious application of conceptual metaphor and blending theory, however, is in lexical semantics, or the study of word meaning (*see* **Lexical Semantics: Overview**). The pervasiveness of metaphoric meanings suggests that metaphoric extension is a major factor in the emergence of new senses, and thus plays an important role in 'polysemy' (*see* **Polysemy and Homonymy**). Polysemy is the phenomenon in which a single word form has many related senses, as in *cut paper*, *cut the budget*, and *cut corners*. Because most words have an array of interrelated senses, metaphor and blending can be used to explain how these different senses can be seen as extensions and elaborations that arise as a function of different contextual circumstances.

Another productive process for creating word senses is 'metonymy,' in which words are used to refer to concepts closely related to their more customary referents (*see* **Metonymy**). For example, in (17), *Shakespeare* refers not to the man, but to the plays authored by the man. Similarly, in (18), *the White House* refers not to the building but to the people who work in the building.

(17) Kenneth loves Shakespeare.

(18) The White House never admits an error.

The interaction of metaphor and metonymy has recently emerged as a major focus of research in cognitive linguistics (see, e.g., Dirven and Poerings, 2003).

Accounts of both metaphor and metonymy are important for the study of how meanings change over time (Sweetser, 1990; Traugott and Dasher, 2001). Conceptual metaphor theory can identify conventional mapping schemes, such as the event structure metaphor, to describe patterns of semantic change, and the experiential grounding of primary metaphors might help explain why some patterns are more pervasive than others. Moreover, conceptual blending theory, with its capacity to describe the integration of general knowledge and contextual circumstances, might be used to address historical, social, and psychological causes of semantic change.

Metaphor: Philosophical Theories

M Arseneault, University of Wisconsin-Madison, Madison, WI, USA

Metaphor and Philosophy

Rather than simply interpreting particular metaphorical expressions, philosophers of language investigate questions such as whether metaphors mean what they do in virtue of semantic content, or whether pragmatic features of expression use and context determine the meaning of metaphors. Answering such questions requires addressing fundamental issues in language and communication such as issues about the limits of literal meaning and the semantic-pragmatic distinction.

Defining Metaphor

Metaphor theorists disagree about which class of expressions constitutes the proper object of an analysis of metaphor. While most metaphor theorists favor live metaphors (metaphors that invite a multitude of interpretations), others such as George Lakoff and Mark Johnson (1980) focus on dead metaphors (metaphors with a relatively fixed meaning) and their role in structuring cognition. At the same time, some metaphor theorists adopt broader definitions while others work with narrower definitions of metaphor.

Metaphor, in its broadest sense (metaphor$_1$), includes most if not all figurative language such that the principle contrast is between metaphorical and literal language. Narrower definitions take metaphor to be only one among many other non-literal tropes. A second type of metaphor (metaphor$_2$), distinct from other non-literal tropes such as irony, metonymy, and synecdoche, is what makes us think of one thing *as* another. Since the very possibility of giving a unified account of metaphor$_1$ is remote, articulating an account of metaphor$_2$ is a more appropriate goal. However, a demarcation problem remains a challenge for any treatment of metaphor$_2$: it must be worked out what it means to say that metaphor$_2$ makes us think of one thing as another in such a way that the difference between metaphor and other non-literal tropes is illuminated.

Delineating Metaphor

The class of metaphorical expressions can be delineated by form or by function. The paradigmatic form of metaphors is the subject-predicate form *S is P*. Metaphorical expressions of this kind are the focus of, for example, John R. Searle's (1993) account of metaphor. According to Searle, a speaker utters an expression of the form *S is P* (*Juliet is the sun*) in order to convey an intended proposition (that Juliet is radiant) of the form *S is R*.

Other accounts of metaphor delineate the class of metaphorical expressions according to a specific understanding of metaphor's function to make us think of one thing as another. For example, the comparison view of metaphor is the view that metaphor functions by comparing two things (Juliet and the sun). Delineating metaphor according to this function assimilates simile to the class of metaphors.

The clear disadvantage of constructing an account of metaphor around any particular form, even paradigmatic forms, is that doing so leaves unexplained other expression forms that have a plausible claim to metaphoricity. Extended metaphors that run the length of a poem and noun-function metaphors of the form *The B of A* (*The countless gold of a merry heart*) are not easily captured by the form *S is P*. Since diverse forms can carry out the same function, functional definitions of metaphor do better at capturing non-paradigmatic forms. Functional definitions explain why we use metaphor (e.g., to compare) in a way that form alone cannot.

The Metaphorical and the Literal

Almost every metaphor theorist accepts the Deviance Thesis: metaphor is essentially nonstandard and deviates either semantically or pragmatically from ordinary literal language. The Deviance Thesis is reflected in the persistent, but challenged (Cohen, 1976), view that metaphors are either literally false or conceptually incongruous.

Deviance and Value

Historically, the deviance of metaphor has been tied to the question of the value of metaphor. Although Cicero (*De Oratore*), Quintilian (*Institutio Oratoria*), and rhetoricians celebrated the deviance of metaphor and its embellishment of language, philosophers John Locke (*Essay concerning human understanding*) and Thomas Hobbes (*Leviathan*) condemned the use of metaphor in philosophical inquiry. If the best chance at arriving at and communicating truth is afforded only by unambiguous literal language use, metaphor's deviance from the literal is therefore suspect. Jean-Jacques Rousseau (*Essay on the origin of languages*) and Friedrich Nietzsche (*On truth and falsity in their ultramoral sense*) attempted to undercut this criticism by arguing that all language is fundamentally metaphorical and championed metaphor's creative function. For a short history of philosophical thought about metaphor, see Johnson (1981) and Kittay (1987).

Deviance: Semantic or Pragmatic?

The cognitive value of metaphor is now generally conceded and metaphor's deviance is considered separately from its value. Contemporary accounts of metaphor characterize its deviance either as a violation of semantic rules or as a violation of pragmatic constraints. Various semantic theories can describe the semantic deviance of metaphor; for example, it can be described as a violation of selection restrictions or as a violation of standard meaning lines between possible worlds. Samuel R. Levin (1977) describes construal mechanisms for assigning interpretations to anomalous or deviant sentences, including the metaphors of ordinary language use and conversation. Metaphors are semantically deviant because they fall outside the class of sentences generated by normal operation of the rules of grammar. According to the metaphor *The stone died,* to be a stone in the metaphoric sense (to be a dunce) is to be similar in characteristics to a stone in the literal sense. The noun *stone* has semantic markers that might include (((Object) (Physical)) (Nonliving) (Mineral)), and the verb *die* has semantic markers that may include ((Process) ((Result) ((Cease to be) (Living)))). The verb has selection restrictions ((Human) or (Animal) or (Plant)), and it is these restrictions that are violated in *The stone died*. Construal rules that sanction the transfer of the feature (Human) to the semantic markers of *stone,* for example, allow us to derive the interpretation that the dunce died.

Jaakko Hintikka and Gabriel Sandu (1990) characterize the semantic deviance of metaphor according to possible world semantics. On this view, meanings are functions from possible worlds to classes of individuals. We can visualize this function by imagining that a notional meaning line connects the individuals, in their respective possible worlds, picked out by the function. Metaphoric meaning is a function that draws nonstandard or deviant meaning lines: they differ from literal meaning lines in that they rely exceptionally heavily in some specific respect on either qualitative or functional similarity. In *The stone died,* the speaker draws the meaning lines of *stone* on the basis of qualitative hardness and immovability.

Pragmatic accounts of metaphor are motivated by the observation that the very same expression (for example, *A storm is gathering*) can be interpreted literally in one context (said of a dark and windy sky) and yet be intended and interpreted metaphorically in another context (said of an anticipated faculty meeting). A full explanation of metaphor, then, must look beyond merely the expression itself to the context of the utterance. H. Paul Grice's theory of conversational implicature provides a pragmatic account of the deviance of metaphor. Conversational implicatures, including metaphor, arise when what is said violates conversational maxims. Grice (1975) says that metaphor violates the conversational maxim of saying only what is true, while Dan Sperber and Deirdre Wilson (1986) argue that it violates the principle of saying only what is relevant. In either case, it is noticing that what is said deviates from these maxims and principles that prompts the hearer to search for an interpretation of the utterance (*Juliet is the sun*) such that the speaker is contributing something true or relevant to the conversation (that Juliet chases away darkness).

Joseph Stern (2000) presents a dual challenge to the Deviance Thesis: unlike Levin, Stern argues that metaphor is not grammatically deviant and, in contrast to Gricean pragmatic accounts, that it is not necessary to first notice that what is said is deviant. Stern suggests that metaphor is a linguistic type representable in the grammar by the operator *Mthat*[Φ]. Like indexicals and demonstratives, metaphors have both a character and a content. The character, or meaning, of a metaphor is the linguistic function from context to content expressions; the content of a metaphor is the propositional content determined by the character (i.e., the interpretation of the metaphorical expression). For example, in an analysis of *Juliet is the sun,* in which the predicate is the metaphorical component, the character of the metaphor picks out the content of {*Mthat*['*is the sun*']}, that is, properties (nourishing, chasing away darkness, etc.) that are associated with the sun.

Stern argues that metaphor is not pragmatically deviant in the way suggested by implicature theorists, insofar as what is conveyed by a metaphor is not inferentially derived against a background of conversational maxims. Instead, the rules of grammar simultaneously make available metaphorical and literal interpretations. Stern and others (Glucksberg and Keysar, 1993; Récanati, 1995) cite evidence that the metaphorical interpretation of the sentence is processed in parallel with, and not serially to, the literal interpretation. It is not necessary to recognize first that what is said violates pragmatic constraints.

Theories of Metaphor

Conditions of Adequacy

Theories of metaphor are successful to the extent that they fulfill certain conditions of adequacy. For example, the proposal that metaphorical expressions are ambiguous fails, because it cannot explain how the meaning of the metaphorical expression depends on the literal meaning of the words used. Unlike ambiguous expressions (example, *bank*), the meaning of the words on one (literal) interpretation stay

'active' and guide the other (metaphorical) interpretation. Other desiderata include explanations of the expressive power and catachretic function of metaphor to remedy gaps in the vocabulary by using words in new ways. Accounts should make sense of the ubiquity of metaphor and explain why some metaphors fail. The more controversial features of metaphor, such as its apparent falsity and nonparaphrasability, must either be accounted for or be explained away. For further discussion of these and other conditions of adequacy, see Nogales (1999).

Aristotle

Aristotle defines metaphor as the transference of a name from genus to species, from species to genus, from species to species, or by analogy. In his influential treatment of metaphor (found in *Poetics* and in *Rhetoric*) we find the seeds of substitution, analogy, and simile theories of metaphor. Under Quintilian's substitution theory of metaphor, a new decorative name is transferred to an object in substitution for its usual plain name, though for merely rhetorical effect. Analogy theories of metaphor have been of particular interest to those interested in the predictive nature of scientific models (Hesse, 1966; Gentner, 1982). Because Aristotle thinks that the function of both simile and metaphor trades on comparison and noticing preexisting similarities, he is also credited as an early proponent of the view that metaphor is a kind of simile. The elliptical simile theory of metaphor specifies that metaphors such as *Time is a child at play* are ellipses of corresponding similes (*Time is like a child at play*). Lynne Tirrell (1991) argues that not all metaphors have corresponding similes, such as metaphors of the form *A is Ψ* (*The moon is envious*). Therefore, although metaphor theorists continue to be tempted to explain metaphor in terms of simile (Fogelin, 1988), elliptical simile theories of metaphor apparently cannot serve as general theories of metaphor.

Interaction Theories of Metaphor

Interaction theories of metaphor have a prominent place among contemporary semantic theories of metaphor. Introduced by I. A. Richards (1936) and Max Black (1962), this kind of theory proposes that instead of simply re-naming or comparing objects, two concepts or systems of associated commonplaces are simultaneously 'interactive.' In *my love is a rose*, the source (also called 'vehicle' or 'focus') *rose* projects an isomorphic set of connotations or believed commonplaces (such as fragility) upon the topic (also called 'tenor') *my love*. Eva Feder Kittay (1987) articulates this interaction in terms of semantic field theory. In this theory, the meaning of a term is a function of its relation (of affinity or contrast) to the other terms in its semantic or conceptual field. For example, the meaning of *midwife* is a function of its semantic field structured according to relations among the agent (midwife), her patient (the mother), and the result (the child). For Socrates's metaphor of teachers as midwives, interactive projection consists of restructuring the relations among the terms in topic field (*teacher*) analogously to those in the source field (*midwife*). Reconceiving the topic in this manner permits the special and controversial creativity of metaphor: metaphor goes beyond exploiting existing similarities to create new similarities or perspectives on the world (perspectival theory of metaphor). Metaphor makes us think of one thing as another because its function is to create a perspective from which we gain an understanding of that which is metaphorically portrayed.

Davidson and Metaphorical Meaning

Donald Davidson (1978) gives what is perhaps the most influential objection to any semantic treatment of metaphor. According to Davidson, the fundamental error of all semantic accounts of metaphor is to read the contents of the thoughts provoked by the metaphor into the content of the expression itself. Davidson denies that the concept of metaphorical meaning is required to explain how metaphor achieves its effect. Sharply distinguishing between what words mean and what words are used to do, Davidson argues that it is the meaning of words that is supposed to explain what can be done with words (and not, for example, the effects achieved by metaphor that explain the meaning of the metaphorical expression). It is because literal meaning and truth conditions, but not metaphorical meaning, can be assigned to sentences apart from particular contexts of use that only literal meaning has genuine explanatory power. If there is no metaphorical meaning, then theories of metaphor can tell us about the effects metaphors have on us, but they do not provide a method for decoding a special content conveyed by the metaphorical expression. See Leddy (1983) and Farrell (1987) for criticisms of Davidson's view, and Crosthwaite (1985) for a defense of Davidson's account.

The psychological study of metaphor has had a major impact on the interdisciplinary understanding of language and thought. Thirty years ago, the topic of metaphor was mostly seen as peripheral to the major focus of research in both linguistics and psychology, because metaphor was primarily viewed as a poetic device that is not representative of how people ordinarily speak or think. But in conjunction with the emergence of cognitive linguistics in the 1970s and 1980s (*see* **Cognitive Linguistics**), psychological research has demonstrated that metaphor is ubiquitous in discourse, can often be easily understood and produced in appropriate social and linguistic contexts, and perhaps most importantly, is both a type of language use and a fundamental scheme of thought. This entry describes the empirical evidence relevant for, and the theories building on, these claims.

The Ubiquity of Metaphor in Language

Metaphor has traditionally been viewed as a distortion of both thought and language, because it involves

Metaphor: Psychological Aspects

R Gibbs, University of California, Santa Cruz, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The psychological study of metaphor has had a major impact on the interdisciplinary understanding of language and thought. Thirty years ago, the topic of metaphor was mostly seen as peripheral to the major focus of research in both linguistics and psychology, because metaphor was primarily viewed as a poetic device that is not representative of how people ordinarily speak or think. But in conjunction with the emergence of cognitive linguistics in the 1970s and 1980s (*see* **Cognitive Linguistics**), psychological research has demonstrated that metaphor is ubiquitous in discourse, can often be easily understood and produced in appropriate social and linguistic contexts, and perhaps most importantly, is both a type of language use and a fundamental scheme of thought. This entry describes the empirical evidence relevant for, and the theories building on, these claims.

The Ubiquity of Metaphor in Language

Metaphor has traditionally been viewed as a distortion of both thought and language, because it involves

the transfer of a name to some object to which that name does not properly belong. Speakers and writers presumably use metaphor as an ornamental feature for poetic and rhetorical purposes (e.g., to say what is difficult to state literally, to express meaning in a vivid manner), rather than to impart fundamental concepts. In each case of metaphorical language, a person aims to present some underlying analogy or similarity in the form of a condensed or elliptical simile. Thus, a metaphor of the 'A is B' form indirectly implies the speaker's intended literal meaning "A is like B in certain respects." For instance, the metaphor 'The car beetles along the road' describes the movement of the car as being like the movement of a beetle. Under this traditional view, metaphor should be infrequent in language, especially in scientific discourse, and people should have more cognitive difficulty when uttering and understanding metaphors than they do when using the equivalent literal speech.

Psychological research has shown, however, that metaphor is a major part of both spoken and written language. Various studies have attempted to quantify the frequency of metaphor use in a variety of contexts. One detailed study examined the use of metaphor in transcripts of psychotherapeutic interviews, in various essays, and in the 1960 Kennedy-Nixon presidential debates and found that people used 1.80 novel and 4.08 frozen metaphors per minute of discourse (Pollio *et al.,* 1977). If one assumes that people engage in conversation for as little as 2 hours per day, a person would utter 4.7 million novel and 21.4 million frozen metaphors over a 60-year life span! A different analysis of the metaphors produced in television debates and news commentary programs showed that speakers use one unique metaphor for every 25 words (Graesser *et al.,* 1989). These, admittedly crude, analyses clearly demonstrate that metaphor is not the special privilege of a few gifted speakers, but is ubiquitous throughout both written and spoken discourse.

However, a closer look at everyday language suggests that these empirical attempts to 'count' instances of metaphor vastly underestimate the pervasiveness of metaphor in people's ordinary speech. Typical frequency counts of metaphor do not include analysis of conventional speech that is motivated by metaphoric modes of thought. Consider the following mundane expressions that people often use in talking about verbal arguments (Lakoff and Johnson, 1980).

Your claims are indefensible.
I've never won an argument with him.
I demolished his argument.
He attacked every weak point in my argument.
His criticisms were right on target.
He shot down all of my arguments.

At first glance, none of these expressions appear to be very metaphoric, at least in the same way that an utterances such as 'The sun is the eye of heaven' might be. Yet, a closer look reveals the systematic metaphoric structuring whereby people think of arguments in terms of wars. We can actually win or lose arguments. We see the person we are arguing with as an opponent. We attack his positions, and we defend our own. We plan and use strategies. We might find certain positions undefensible, requiring us to take new lines of attack. Each of these things do not simply reflect the way we talk about arguments: we actually argue as if we were in a war. Our understanding of argument as war is active and widespread, but this concept is so deeply entrenched in our ordinary conceptual system that we tend to miss its metaphorical character.

Cognitive linguistic research has suggested that there are perhaps hundreds of conceptual metaphors, such as ARGUMENTS ARE WARS, that structure our everyday experience, and that they are found in a wide variety of conceptual domains (Gibbs and Steen, 1999; Kövecses, 2002; Lakoff and Johnson, 1999). Linguistic analyses do not typically quantify the number of verbal metaphors, and the conceptual metaphors underlying them, that may be present in any one sample of speech or text. But one psychological study of the narratives women produced when describing their experiences recovering from cancer showed that conventional metaphoric language was employed more than 6 times per minute, and that only 22 conceptual metaphors underlay the vastly different metaphoric expressions these women produced, especially in their talk of emotion (Gibbs and Franks, 2002). Conceptual metaphors seem to be ubiquitous in the ways people talk of their experiences. One question that has generated a great deal of debate within psychology is whether these instances of conventional metaphor necessarily reflect anything about the metaphorical nature of many abstract concepts.

Metaphor Understanding: The Standard View

The traditional belief that metaphor is deviant suggests that metaphors should be more difficult to interpret than literal speech. The most famous proposal along this line comes from H. Paul Grice's theory of conversational implicature (Grice, 1989) (also see Grice, H. Paul (1913–1988); *see* **Implicature**). Grice argued that the inferences needed to understand

nonliteral meaning are derived from certain general principles or maxims of conversation that participants in talk-exchange are mutually expected to observe (Grice, 1989) (*see* **Maxims and Flouting**). Among these are expectations that speakers are to be informative, truthful, relevant, and clear in what they say. When an utterance appears to violate any of these maxims, as in the case of metaphor, listeners are expected to derive an appropriate 'conversational implicature' about what the speaker intended to communicate in context, given the assumption that he or she is trying to be cooperative (*see* **Cooperative Principle**).

Grice (1989) more specifically suggested what has become known as the 'standard pragmatic model' for understanding indirect and nonliteral meanings, including metaphor. In this view, understanding metaphor is accomplished in a series of steps: (1) analyze the literal meaning of an entire expression, (2) compare this literal meaning to the context, (3) if the literal meaning is appropriate, then stop, otherwise (4) derive an alternative meaning that makes the speaker's/writer's utterance sensible in the context, given the cooperative principle. This rational account suggests, then, that metaphors are understood as conversational implicatures and should take additional time to comprehend over that needed to interpret literal speech that is appropriate to the context.

Psychological Tests of the Standard View

How accurate is the standard view as a psychological theory of metaphor understanding? First, the results of many reading-time experiments in psycholinguistics show that people do not always require additional mental effort to comprehend many kinds of figurative utterances, as compared with so-called literal speech (Gibbs, 1994, 2002). Listeners/readers often take no longer to understand the figurative interpretations of metaphor (e.g., 'billboards are warts on the landscape'), metonymy (e.g., 'The ham sandwich left without paying') (*see* **Metonymy**), sarcasm (e.g., 'You are a fine friend'), idioms (e.g., 'John popped the question to Mary'), proverbs (e.g., 'The early bird catches the worm'), and indirect speech acts (e.g., 'Would you mind lending me five dollars?' *see* **Speech Acts, Literal and Nonliteral**) than to understand equivalent literal expressions, particularly if these are seen in realistic linguistic and social contexts. Appropriate contextual information provides a pragmatic framework for people to understand metaphoric utterances without any recognition that these utterances violate conversational norms. In fact, psychological studies have specifically shown that people do not need to find a defective literal meaning before searching for a nonliteral meaning. For example, people apprehend the metaphoric meanings of simple comparison statements (e.g., 'surgeons are butchers') even when the literal meanings of these statements fit perfectly with the context (Glucksberg *et al.,* 1982). Even without a defective literal meaning to trigger a search for an alternative meaning, metaphor can be automatically interpreted.

These experimental findings from psycholinguistics are damaging to the general assumption that people understand metaphor as violations of conversational maxims. Similar psychological mechanisms appear to drive the understanding of both literal and metaphoric speech, at least insofar as early cognitive processes are concerned. Everyone agrees that people may sometimes take a good deal of time to process novel poetic metaphors, for example. Studies have shown, in fact, that conventional, or familiar, metaphors can be understood more quickly than novel expressions (Katz and Ferretti, 2001). Yet the additional time needed to understand novel metaphors is not necessarily due to a preliminary stage during which the literal meaning for an entire utterance is first analyzed and then rejected. Listeners may take longer to understand a novel expression, such as 'The night sky was filled with molten silver,' because of the difficulty in integrating the figurative meaning with the context, and not because listeners are first analyzing and then rejecting the expression's literal meaning (Schraw, 1995).

Many psychologists have gone on to argue that even if metaphor does not necessarily demand extra cognitive effort to understand, people may still analyze literal, conventional, or salient, aspects of word meaning during immediate metaphor comprehension (Blasko and Connine, 1993; Giora, 2001). Some studies, which measure the meanings activated during each part of the moment-by-moment process of linguistic understanding, suggest that comprehending familiar and novel metaphors engages different linguistic processes. Analysis of literal word meaning still precedes metaphorical meaning during novel metaphor understanding, with both types of meaning arising in parallel during familiar metaphor processing. Other studies that assessed people's speeded judgments about the sensibility of different word strings at different moments find no difference in the comprehension speed for literal and figurative strings (McElree and Nordlie, 1999). This lack of time-course differences is inconsistent with the claim that metaphoric interpretations are computed after a literal meaning has been analyzed, and suggest that literal and metaphoric interpretations are computed in parallel.

Although these research findings imply that metaphor processing is not secondary to literal understanding, psycholinguists are, again, careful to note that people may be biased toward initially interpreting the literal, or salient, meanings of metaphoric statements in cases of novel metaphor (Giora, 2001). Yet others argue that even if some linguistic meanings (e.g., literal or metaphoric) are created sooner during metaphor processing, these findings do not imply that entirely different mental processes operate to produce these different meanings (Gibbs, 2002). Different kinds of meaning may arise from a single linguistic process. The fact that scholars label one kind of meaning 'literal' and another 'metaphoric doesn't necessarily indicate that different processes operate (such as a literal processing mode and a metaphoric processing mode) as people access these meanings (either in a serial or parallel manner).

More recent theories of figurative language understanding, which are more general than metaphor theories *per se*, suggest that people may initially access a word's interpretation that can be compatible with both its literal and metaphoric meanings (Frisson and Pickering, 2001). Over time, however, people use context to home in on the word's appropriate metaphoric meaning, where the homing-in process is faster when the preceding context is strong, and slower when the preceding context is neutral. In this way, context does not operate to distinguish between different literal and metaphoric meanings, as assumed by most theories (such as in the standard model), but functions to change an underspecified, or highly general meaning, into a contextually appropriate, specific interpretation which may be metaphorical.

A different theory embraces the notion of 'constraint satisfaction' to provide a comprehensive model of the different sources of information that constrain metaphor understanding (Katz and Ferretti, 2001). Under this view, understanding a metaphoric utterance requires people to consider different linguistic (e.g., people's familiarity with words and phrases) and nonlinguistic (e.g., related to specific context) information that best fits together to make sense of what a speaker or writer is saying. These different sources of information are probabilistically evaluated, and combined to offer a most likely 'winning' meaning for a metaphor. A constraint satisfaction model may have the flexibility to account for a wide variety of metaphor processing data that seems to differ depending on the familiarity or conventionality of the expression, the context in which it is encountered, and the speaker's/writer's likely intentions in using metaphorical language.

In summary, there has been a great deal of psychological research devoted to the general question of whether metaphorical language requires additional cognitive effort to understand, compared to nonmetaphorical speech. The findings of these widely varying studies strongly imply that metaphors are not deviant and do not necessarily take more time to understand, but that more subtle factors, such as the familiarity of the expression and the context in which it is used, can shape the time-course of metaphor understanding. Many studies now situate metaphor understanding within a more comprehensive view of linguistic processing that does not posit specialized mechanisms for interpreting metaphors, even if these expressions often convey distinctive kinds of meanings (Kintsch and Bowles, 2002), and which specifically relies on cognitive mechanisms, such as suppression, that are employed widely in all aspects of language processing (Gernsbacher and Robertson, 1999).

Psychological Models of Metaphor Understanding

A great deal of research has been devoted to the specific processes involved in understanding metaphorical meaning, beyond the general question of whether metaphors are more difficult to comprehend than literal speech. These studies have explicitly examined the ways that the A, or target, and B, or vehicle, terms interact to produce metaphorical meaning. A long-standing assumption in many academic fields is that we understand metaphors by recognizing the ways that topic and vehicle terms are similar. Thus, in understanding the metaphor 'Juliet is the sun,' listeners are presumed to figure out the properties of both Juliet and the sun that are similar.

But psychological studies indicate that metaphor comprehension does not demand that the topic and vehicle terms share properties or associations (Camac and Glucksberg, 1984). This finding is supported by many studies showing that metaphors have directional meaning. If metaphorical meaning arises from the overlap of the semantic features of topic and vehicle, expressions such as 'The surgeon is a butcher' and 'The butcher is a surgeon' should have similar metaphoric meanings. But this is clearly not the case. The similarity that arises from the comparison of a topic and vehicle does not produce metaphorical meaning. Instead, similarity is created as an emergent property of understanding metaphor. Thus, many psychological studies have demonstrated that novel features emerge from metaphor comprehension that are not salient in one's separate understanding of the topic or vehicle (Gineste *et al.,* 2000). This idea is consistent with the popular, but somewhat vague, interactionist theory of metaphor (Black, 1979), which argues

that the presence of the topic stimulates a listener to select one of the vehicle's properties so as to construct a 'parallel implication complex' that may induce changes in one's understanding of both the topic and vehicle. In general, psychological studies provide strong evidence supporting the idea that metaphor cannot be reduced to rule-governed extensions or variations of the topic's and vehicle's literal meanings.

Psychologists disagree, however, about the cognitive mechanisms involved in feature emergence during metaphor understanding. The two main proposals state that metaphorical mappings between concepts from dissimilar domains can be accomplished by either comparison or categorization processes. Traditional comparison theories posit that metaphor understanding demands a mapping of low-salient features from the source domain with high-salient features of the target domain (Miller, 1979). But understanding many metaphors, such as 'Men are wolves,' seems to involve the activation of semantic features that are not typically associated with either the source or target domain until after the metaphor has been understood (Ortony, 1979). Gentner's 'structure-mapping' theory of analogy and metaphor avoids this problem by suggesting that people begin processing a metaphor by first aligning the representations of the source and target domain concepts (see Gentner *et al.,* 2001). Once these two domains are aligned, further inferences are directionally projected from the source to the target domain. Finally, new inferences arise within the target domain, reflecting relational, and not just feature-specific, aspects of the metaphor comprehension processes. Experimental evidence in support of this comparison view shows, for instance, that people infer relational, but not feature-specific, meanings when interpreting metaphors (Gentner *et al.,* 2001). For instance, when people read 'Plant stems are drinking straws,' they infer that both plants and straws convey liquid to nourish living things, and not just that both plants and straws are long and thin (i.e., object commonalities). Other research indicated that metaphors that express relational information (e.g., 'Plant stems are drinking straws') are viewed as being far more apt than those that only map object features ('Her arms were like twin swans').

An alternative view claims that metaphors are better understood via categorization processes, as class-inclusion, rather than comparison, statements (Glucksberg, 2001). For example, the statement 'Yeltsin was a walking time bomb' asserts that the former Russian President is a member of a category that is best exemplified by time bombs. Of course, time bombs can belong to several other categories, such as the weapons used by terrorists. But in the context of talking about people, time bombs best exemplify the abstract category of 'things that explode at some unpredictable time in the future and cause a lot of damage.' In this way, metaphors reflect '*ad hoc*' categories and refer at two levels: the concrete level (i.e., an explosive device) and a superordinate level (i.e., the properties of time bombs).

One implication of the class-inclusion model is that it suggests that the topics and vehicles, or target and source domains, in metaphors play different but interactive roles in metaphor comprehension. For example, the word 'snake' evokes different meanings in the phrases 'my lawyer is a snake' and 'the road was a snake.' In this way, metaphor topics provide dimensions for attribution, while vehicles provide properties to be attributed to the topic. Psychological evidence supporting this position showed that in a reading-time study, presenting people first with a topic term that is highly constrained reduces the time needed for the subsequent processing of a metaphorical statement, in contrast to when people are first presented with a less-constrained topic (Glucksberg, 2001). Furthermore, presenting people with an unambiguous vehicle primes subsequent metaphor comprehension, in contrast to what happens when they are presented with an ambiguous vehicle term. This pattern of data illustrates how the level of constraint is an important feature of metaphor topics, while the degree of ambiguity is an important characteristic of metaphor vehicles. Comparison models of metaphor understanding are unable to explain the importance of constraint and ambiguity, because they assume that metaphor comprehension always begins with an exhaustive extraction of the properties associated with both topics and vehicles. Having advance knowledge about either the topic or vehicle should presumably, then, prime metaphor processing. However, the categorization view correctly predicts that only advanced knowledge about highly constrained topics and unambiguous vehicles facilitates metaphor comprehension, a finding that is most consistent with the claim that metaphor understanding involves creating a new, *ad hoc* category and not merely comparing one's knowledge about topic and vehicle domains.

A proposal titled the 'career of metaphor' theory combines aspects of both the comparison and categorization views (Gentner and Bowdle, 2001). This theory claims that there is a shift in the mode of mappings from comparison to categorization processes as metaphors become conventionalized. For instance, novel metaphors such as 'Science is a glacier' involve base terms, such as 'glacier,' with a literal source (i.e., 'a large body of ice spreading outward over a land surface'), but no relational metaphoric sense (i.e., 'anything that progresses slowly but steadily'). People

comprehend novel metaphors as comparisons in which the target concept (e.g., 'science') must be structurally aligned with the literal base concept (e.g., 'glacier'). In some instances, the comparison process may lead to the induction of a novel metaphor category. On the other hand, conventional metaphors can be understood either by comparison or categorization processes. For example, the metaphor 'A gene is a blueprint' has two closely related senses (e.g., 'a blue and white photographic print detailing an architect's plans' and 'anything that provides a plan'). The relations between these two senses make the conventional base term polysemous (i.e., semantically related literal and metaphoric meanings). As such, conventional metaphors may be understood by matching the target concept with the literal base concept (a comparison process) or by viewing the target concept as a member of the superordinate metaphoric category named by the base term (a categorization process).

Metaphor in Thought

Most of the psychological research on metaphor has focused on how it is used and understood within language, and has assumed that metaphorical meaning is created *de novo*, and does not reflect preexisting aspects of how people ordinarily conceptualize ideas and events in terms of pervasive metaphorical schemes. But in the past 20 years, various linguists, philosophers, and psychologists have embraced the alternative possibility that metaphor is fundamental to language, thought, and experience. Cognitive linguists, for instance, claim that metaphor is not merely a figure of speech, but is a specific mental and neural mapping that influences a good deal of how people think, reason, and imagine in everyday life (Lakoff and Johnson, 1999). Evidence supporting this claim comes from linguistic research on the historical evolution of what words and expressions mean, the systematicity of conventional expressions within and across languages, novel extensions of conventional metaphors, studies on polysemous word meaning, and nonverbal behaviors such as gesture (Gibbs, 1994; Lakoff and Johnson, 1980, 1999).

However, psychologists have been critical of much of this work and its possible implications for theories about conceptual structure and metaphor understanding. First, most of the evidence for metaphorical thought, or conceptual metaphor, comes from purely linguistic analyses, and psychologists have expressed deep skepticism about these claims on both methodological and theoretical grounds, especially with regard to linguists' heavy reliance on their own linguistic intuitions (Murphy, 1996). Second, some psychologists argue that conceptual metaphor theory is unfalsifiable if the only data in its favor is the systematic grouping of metaphors linked by a common theme (Vervaeke and Kennedy, 1996). Consider again the conceptual metaphor ARGUMENT IS WAR (Lakoff and Johnson, 1980), which presumably motivates conventional expressions such as 'He attacked my argument' and 'He defended his position.' Cognitive linguistic research suggests that any expression about argument that does not fit the WAR theme is usually seen as evidence for another theme, such as WEIGHING, TESTING, or COMPARING. This implies that no linguistic statement can be brought forward as evidence against the ARGUMENT IS WAR metaphor, which makes the basic tenet of conceptual metaphor theory impossible to falsify. Finally, some psychologists argue that many conventional expressions viewed as metaphorical by cognitive linguists are really not metaphorical at all, but are treated by ordinary speakers/listeners as literal speech (Glucksberg, 2001). Simple expressions like 'He was depressed' are entirely literal, and may not be motivated by a conceptual metaphor such as SAD IS DOWN, because they only reflect something about the polysemous nature of meaning (e.g., 'depression' can be used to talk about either physical depression or emotional depression).

Psychological Studies on Conceptual Metaphor

Despite the skeptical reaction of some psychologists to the idea of metaphorical thought, or conceptual metaphor, there is a great deal of psychological evidence supporting the claim that many aspects of people's abstract concepts and reasoning processes are shaped by enduring conceptual metaphor. Studies show, for instance, that conceptual metaphors influence the ways people conceive of various abstract domains, such as emotions, minds, politics, advertising, scientific theories, the self, morality, learning, and problem-solving (Gibbs, 1994; see Steen and Gibbs, forthcoming, for reviews). Most of these studies demonstrate that providing people with a particular metaphorical construal of some domain (e.g., that EMOTIONS ARE CONTAINERS) can facilitate the way they learn new information, solve problems, and make decisions, if the newly encountered material has a similar metaphorical structure. At the same time, whereas switching from one conceptual metaphor to another may require more cognitive effort in some situations (Langston, 2002), people typically have multiple metaphorical ways of conceiving of most abstract ideas (e.g., THEORIES ARE BUILDINGS, THEORIES ARE FABRIC (Gibbs, 1994). This multiplicity of metaphorical schemes

provides another source of evidence for the idea that a good deal of ordinary thought is shaped by metaphor.

Even if people seem able to think metaphorically about various domains, many psychologists and especially many psycholinguists are skeptical about whether conceptual metaphors are normally recruited during people's ordinary comprehension of language (Glucksberg, 2001). These critics find it difficult to believe that conceptual metaphors play much of a role in how people interpret verbal metaphors such as 'Surgeons are butchers' or 'Lawyers are snakes.' To a large extent, the debate over conceptual metaphor settles into two camps: those scholars studying novel metaphors and those studying conventional language that may reflect different conceptual metaphors (e.g., 'He attacked my argument' for ARGUMENTS ARE WARS, 'Our relationship hit a dead end street' for LIFE IS A JOURNEY, and so on). Thus, different approaches to the psychology of metaphor understanding are oriented toward different types of metaphorical language. A likely possibility is that conceptual metaphor may have a strong influence on some aspects of verbal metaphor use, but not on others.

In fact, there is a large body of evidence from psychological studies, employing different methods, that clearly demonstrates that (a) people conceptualize certain topics via metaphor, (b) conceptual metaphors assist people in tacitly understanding why metaphorical words and expressions mean what they do, and (c) people access conceptual metaphors during their immediate, online production and comprehension of conventional and novel metaphors. This work includes studies investigating people's mental imagery for conventional metaphors, as in idioms and proverbs (Gibbs and O'Brien, 1990), people's context-sensitive judgments about the figurative meanings of idioms in context (Nayak and Gibbs, 1990), people's immediate processing of idioms (Gibbs *et al.,* 1997), people's responses to questions about metaphorical expressions about time (Boroditsky and Ramscar, 2002; Gentner *et al.,* 2002), readers' understanding of metaphorical time expressions (McGlone and Harding, 1998), and studies looking at the embodied foundation for conventional metaphoric language (Gibbs *et al.,* 2004).

To briefly give a few examples from these psycholinguistic experiments, studies show that people have a complex metaphorical understanding of many abstract domains, which partially motivates everyday reasoning and language use. For instance, people conceive of the domain of emotions metaphorically, based partly on their embodied experiences of emotions, such that they tacitly know that phrases like 'blow your stack' and 'flip your lid' are motivated by the conceptual metaphor of ANGER IS HEATED FLUID IN A CONTAINER. This metaphorical understanding of anger influences people's judgments about the degree to which someone experiences anger and about the best use of different metaphorical phrases in context (Nayak and Gibbs, 1990). At the same time, people's tacit knowledge of conceptual metaphors constrains the specific mental images they can form for verbal metaphors, and the specific meanings they believe these metaphors express (e.g., that 'blow your stack' means to get very angry while the person is feeling internal pressure, and the expression of the anger is unintentional and forceful) (Gibbs and O'Brien, 1990). In fact, many conventional phrases and idioms, long thought to be dead metaphors, retain much of their metaphorical meaning precisely because they continue to be linked to enduring conceptual metaphors. Finally, priming studies suggest that reading a conventional metaphorical phrase, such as 'John blew his stack,' quickly accesses the conceptual metaphor (ANGER IS HEATED FLUID IN A CONTAINER) that partly motivates why this expression has the particular metaphorical meaning it conveys (Gibbs *et al.*, 1997). Reading another expression with roughly similar metaphoric meaning, such as 'John bit her head off,' activates a different conceptual metaphor (ANGER IS ANIMAL BEHAVIOR), giving rise to the creation of these metaphorical expressions.

The debate over the role that metaphorical thought may play in a psychological theory of verbal metaphor use will likely continue. Once more, it seems inevitable that several of the different approaches to metaphor within linguistics and psychology will become part of a more comprehensive theory of metaphor. Yet it is already evident that the traditional views of metaphor as deviant, ornamental aspects of language and thought no longer are tenable and that psychological studies have provided excellent reasons to believe that metaphor is a fundamental part of the ways people speak and think.

Metaphor: Stylistic Approaches

G Steen, Vrije Universiteit, Amsterdam, The Netherlands

Introduction

Stylistic approaches to metaphor used to take metaphor as one of the most important rhetorical figures of speech that could characterize a particular style. A representative illustration is provided in the classic textbook *Style in fiction*; the authors, Leech and Short (1981: 79), offered a checklist for stylistic features: metaphor is included in the section on tropes, together with metonymy, synecdoche, and other figures of speech defined by 'strange meaning' or 'semantic deviation.' In contrast, schemes, the other main group of rhetorical figures of speech, are defined by repetition of form, or 'structural parallelism,' such as chiasmus and rhyme. According to Leech and Short, schemes and tropes together constitute one of the four dimensions of style, the other three dimensions involving features of vocabulary, grammar, and text (still called cohesion and context). This stylistic angle on metaphor, representative of most mainstream positions, hence distinguished metaphor from ordinary meaning and its linguistic basis (vocabulary, grammar, and text) and treated it as a separate class of phenomena requiring special treatment.

Since the publication of *Style in fiction*, however, the perception of the relation between metaphor, style, and language has dramatically changed. Metaphor – once regarded as the rhetorical figure par excellence, being parasitic on ordinary or literal meaning, deviant, dangerous, and misleading – is now seen as one of the foundations of all language, and its use, being constitutive of meaning, is seen as normal, grounded in experience, and offering guidance to linguistic expression. The presence of metaphor as such is not necessarily indicative of any particular style, as it used to be. Instead, it is part of common, everyday language, as is attested by the many metaphorical forms (words, phrases, morphemes, and even grammatical constructions) that are entirely conventional. The publication that has been pivotal in this change of perspective, Lakoff and Johnson's *Metaphors we live by* (1980) (cf. Lakoff and Johnson, 1999), provides a wealth of examples of the ubiquity of metaphor in language, including conventional talk of *love* as 'a journey,' *argument* as 'war,' *theories* as 'buildings,' *understanding* as 'seeing,' and *life* as 'a gambling game.'

The new view holds that metaphor may still be exploited for rhetorical purposes. However, the present-day stylistician has to analyze the specifics of this exploitation against the background of the more general patterns of metaphor pervading language and its use. This means that classic studies of metaphor in literary style, such as David Lodge's *The modes of modern writing* (Lodge, 1977), are not invalidated by the new approach, since they also include the stylistic use of conventional metaphor, but their theoretical and empirical suggestions do require more extensive investigation of the relation between metaphor in style and metaphor in all language use (Steen and Gibbs, 2004). That is the direction taken by many recent stylistic approaches to metaphor. What has remained unchanged between the traditional and the contemporary views of metaphor is the awareness of metaphor's cognitive import. Aristotle, Giambattista Vico, Percy Bysshe Shelley, Friedrich Nietzsche, I. A. Richards, Max Black, and Paul Ricoeur, to name but a few of the numerous metaphor theorists over time, have all pointed to the conceptual or cognitive basis of metaphor: metaphor draws attention to similarities or correspondences between entities or domains that are fundamentally distinct. This happens in everyday talk of sports in terms of war, or lust in terms of hunger. But it also motivates the more spectacular or subtle stylistic exploitations of metaphor, as in Aristotle's discussion of Homer's comparison between old age and wheat stubble (see Mahon, 1999).

A concomitant constancy between old and new theories of metaphor is the derived attention to its social, affective, and aesthetic import as the corollary of its conceptual structure. When people are compared to lions or to mice, they are compared to animals with a higher or lower status, and this has the accompanying social effect of praising or criticizing them. In addition, when this happens perversely, it can produce irony and humor, and perhaps some admiration for the aesthetic wit of the usage, depending on the occasion and the perception of the producer's rhetorical intentions. But perfectly ordinary metaphorical expressions, such as *time is money*, also have social and affective implications, which are part and parcel of the stylistic effect of a metaphor. The mechanisms of these effects have been studied by experimental psycholinguists (e.g., Gibbs, 1994) and by conversational analysts and applied linguists (Cameron and Low, 1999). Stylistic approaches, however, are typically more focused on the functional analysis of metaphor, effects on cognition being left to the behavioral sciences.

Definition

Metaphor as a feature of style is a subclass of all metaphor in language and its use. The stylistic definition consequently has to distinguish metaphor as a stylistic device from metaphor as a more general linguistic mechanism. The stylistic definition hence approaches metaphor as one typical characteristic of a particular language variety that is relatively individual or idiosyncratic, such as the style of an individual work or author, or more generally, language user. For instance, the metaphors of politicians such as Tony Blair or George W. Bush are important ingredients of their style. But metaphor may also be characteristic of broader patterns of usage across groups of language users, including, for instance, sports reporters or songwriters. Such encompassing language varieties, or registers, are typically based in more general classes of usage that transcend individual styles. However, those manifestations of metaphor will also be considered as having a stylistic interest because of their typical role in clearly identifiable registers and genres.

As suggested previously, the difference with traditional stylistic approaches is that metaphor today is not just taken as a rhetorical device that should be opposed to ordinary vocabulary, grammar, and texture. Instead, the use of metaphor in those non-rhetorical provinces of language may also have a stylistic function. Thus, when a language user has a preference for one set of metaphors over another, both of which are completely conventional parts of the language, the preference may still be seen as a feature of that language user's style, regardless whether it is glaringly prominent or revealed only by careful scrutiny or even statistical analysis.

The new, so-called cognitive-linguistic approach to metaphor launched by Lakoff and Johnson (1980, 1999) defined metaphor as a mapping between two semantic domains. Such crossdomain mappings can motivate varying numbers of systematically related linguistic expressions of a metaphorical kind. For instance, 'love' can be metaphorically conceptualized as a natural force, and we can hence say that somebody was *swept off his feet* or *bowled over* by another person. Such conventional metaphorical expressions are part and parcel of everyday language, and they have overt stylistic implications when they are used relatively deliberately as metaphors, or when new aspects of the mapping are exploited for discursive purposes. An example may be provided by rock singer Neil Young's lines "You are like a hurricane, there's foam in your eyes, and I'm getting blown away." But less prominent patterns of usage would be equally relevant, as when people consistently use one set of metaphors for marriage as opposed to other possible sets, either in conversations or in psychotherapy (Gibbs, 1994).

The cognitive-linguistic approach to metaphor has been developed in various ways (cf. Gibbs and Steen, 1999; Dirven and Pörings, 2002), with one line of theorizing, called 'conceptual integration theory' or 'blending theory,' offering a competing model that utilizes more than two conceptual domains or spaces (Fauconnier and Turner, 2002; cf. Grady *et al.*, 1999). The cognitive-linguistic approach has also given rise to alternative models, in particular in psycholinguistics (Glucksberg, 2001). These alternative models define metaphor in different ways, mainly questioning the basic assumption that crossdomain mappings are understood by means of some form of comparison (Giora, 2001; cf. Croft and Cruse, 2004). It should also be noted that the cognitive-linguistic definition of metaphor as a crossdomain mapping in conceptual structure allows for the possibility that not all metaphor in thought is expressed by metaphor in language. Crossdomain mappings in thought may also be realized by similes, analogies, extended metaphors, megametaphors, allegories, and parables, to mention just the most well-known alternatives (Steen and Gibbs, 2004). Therefore, stylistic approaches to metaphor have to be explicit about their preference for either the linguistic, formal definition of metaphor, which takes metaphor as one specific rhetorical figure, or the more general, cognitive definition, which takes metaphor as a figure of thought, which in turn includes a whole range of rhetorical figures and even text forms.

The advantage of adopting the more encompassing definition is its capacity for contrasting the stylistic functions of these various rhetorical forms. Thus, when a crossdomain mapping is expressed as a metaphor, it may slow down or even prevent the activation of a comparative interpretation strategy, whereas its expression as a simile may facilitate such a strategy (see Gentner and Bowdle, 2001). This, in turn, may decrease or increase the recognition and hence the experienced prominence of a metaphor in style.

There is yet another complication with the definition of metaphor. It would be incorrect to suggest that all linguists (and stylisticians) have embraced the cognitive-linguistic definition of metaphor that also includes all conventionalized metaphorical meaning. For instance, Jackendoff (2002), the most important representative of the generative-grammatical approach to semantics, believed that this went too far, and abided by the more restricted definition of metaphor as the relatively deliberate rhetorical figure. This means that, in effect, that there are currently three definitions of metaphor in style:

1. The restricted rhetorical definition of metaphor as active or deliberate metaphor.
2. The broader cognitive-linguistic definition, which focuses on metaphor as a specific linguistic form, whether it is active and deliberate.
3. The most encompassing, cognitive, definition, which defines metaphor as a crossdomain mapping in conceptualization that may be realized by various rhetorical figures, of which linguistic metaphor is one that has to be contrasted with simile, analogy, and so on.

History

The cognitive-linguistic approach emphasizes the cognitive and systematic nature of metaphor and therefore highlights its ubiquity and conventionality. This is an encompassing, linguistic approach, which does not take metaphor as just a stylistic device in the rhetorical sense of the term. To many scholars, the cognitive-linguistic approach has replaced older views of metaphor, which used to limit metaphor to the rhetorical phenomenon – that is, to those metaphors that are active – thereby drawing attention to their deviance as well as to the probability that they are deliberate. The cognitive-linguistic view argues in particular that it has taken over from the conceptualization prevailing in the 1960s, of metaphor as necessarily involving grammatical deviance, research showing that many metaphorical expressions in language are not deviant but rather are the norm. Similarly, not all metaphors uncovered by the cognitive-linguistic approach require pragmatic inferencing, as was argued in the 1970s by John Searle and H. P. Grice, but may be understood with reference to conventionalized semantic mappings. The best overview of these different positions is still provided by Ortony (1993).

Another series of issues that has been important in the history of metaphor is the debate over the questions of whether metaphor is a matter of substituting a metaphorical expression for another, presumably literal one; whether it is a matter of comparison between unlike phenomena; or whether it is a matter of interaction between two distinct ideas (for an overview, see, e.g., Gibbs (1994)). Modern developments in cognitive linguistics have come to take a liberal view of the notion of correspondences in metaphor as a cross-domain mapping. This now includes both pre-existing and perceived similarity between phenomena (comparison), and interaction between conceptual structures (interaction), as is, for instance, summarized by Kövecses (2002) in his cognitive-linguistic introduction to the field. This broader view of metaphor in cognitive linguistics goes back as far as the classic position of Aristotle, who also saw metaphor as based in correspondences. At the same time, the new view re-establishes contact with the widespread structuralist views of metaphor as based in similarity, versus metonymy as based in contiguity (cf. Barcelona, 2000; Dirven and Pörings, 2002; Panther and Radden, 1999). It has led to new questions about the analysis of many metaphorical expressions. For instance, do we see time **as** money (metaphor) or do we see time **via** or **through** money (metonymy)?

A third historical issue has to do with the terminology for metaphor analysis. Cognitive linguistics and other cognitive scientific approaches of metaphor have introduced the distinction between 'source' and 'target' domains, whereby the source domain includes the knowledge of the metaphorically used concepts and words and the target domain includes the knowledge of the nonmetaphorically used concepts and words. These terms are now in competition with the traditional terminology, which calls the source domain the 'vehicle' and the target domain the 'tenor.' Yet another tradition talks about the source domain vocabulary as the metaphor 'focus,' and the target domain vocabulary is regarded as the 'frame.' Thus, in an expression such as *Time is money*, 'time' is called the tenor or a term from the target domain and 'money' is called the vehicle or a term from the source domain; 'money' is the focus, whereas 'time is . . .' is called the frame. It is not clear which terminological tradition will prevail.

Classes of Metaphor

Metaphor can exhibit many different linguistic forms. Most attention has been paid to metaphorically used words, with some attention being paid to the various word classes, such as nouns, verbs, and adjectives (e.g., Goatly, 1997; Steen, 2002; Cameron, 2003). However, metaphor is also important for the study of phraseology, exhibiting connections with idiom and with the revitalization of allegedly dead metaphor (Naciscione, 2001), and systemic-functional grammarians have performed extensive study of grammatical metaphor and its stylistic and discursive functions (Simon-Vandenbergen *et al.*, 2003).

Metaphor can also play a role in all kinds of meaning. For instance, study has been made of common source and target domains, which are typically (but certainly not exclusively) concrete and abstract, respectively. Kövecses (2002) listed as common source domains the human body, animals, machines and tools, buildings and construction, plants, games

and sports, and so on; he listed as common target domains concepts such as life, time, death, emotions, thought, society, and so on. The study of the metaphorical conceptualization and expression of emotions, in particular, has been rather detailed and advanced (Kövecses, 2000). Particular combinations of source and target domains lead to well-known classes of metaphor, such as personification, concretization, or abstraction. One very specific class of metaphor involves the crossing of sensory modalities, producing synesthesia: we conventionally talk of *loud colors* and *dark sounds,* among many other possibilities.

The functions of metaphor in discourse are also various. Ernest Rutherford's model of the atom in terms of the solar system has a descriptive and explanatory function in science, as well as a didactic function in education. Psychologists have employed various metaphorical models of the mind, ranging from steam engines to computers. But highly conventional metaphors may also function as topic management devices in conversation. And highly innovative metaphors may function as the acme of artistic pleasure (for one list of functions of metaphor, see Goatly (1997)).

Further classification of metaphors in style is possible by considering their combination with other rhetorical figures. Oxymoron and paradox often require metaphorical interpretation to resolve their logical contradiction, as in *sweet sorrow*. Hyperbole and litotes often combine with metaphor to enlarge or diminish the object of comparison, as when a boxer is called 'Hurricane' or 'Raging Bull.' This leads to a consideration of the possibility of the laudatory as opposed to the critical use of these scales of comparison, involving the addition of irony, sarcasm, and humor. Consider W. H. Auden's phrase of 'committing a social science,' a metaphorical phrase that turns social science into a crime. Similar combinations are possible of metaphor with schemes of form, involving parallelism and deviation in sound and grammar, as often happens in newspaper headlines or nicknames (think of tennis player Pete Sampras, who was called 'Pistol Pete').

Application

Metaphorical Utterances

Metaphor in style has a wide range of manifestations, including, to begin with, its striking use in specific utterances. Famous metaphorical quotations may illustrate this phenomenon, from the Bible's *The Lord is my shepherd* through Karl Marx's view of religion as *the opium of the people*, to George W. Bush's repeated use of *the axis of evil* to refer to Iran, Iraq, and North Korea. Specific metaphors may also be conventionalized parts of the language in the form of sayings, such as *Time is money* or *How time flies*. In discourse, these may be used in their regular form to conventional effect, or they may be exploited for special purposes, as when Bob Dylan writes "Time is a jet plane, it moves too fast." When used in their regular form, metaphors often serve in conversations as topic management devices, signaling that one topic is being terminated and the conversation is moving on to another.

Some sayings are not metaphorical by their linguistic structure alone; strictly speaking, rather, they turn metaphorical only when they are applied to specific situations, such as when *Blind blames the ditch* is used for an accident without any blind people or ditches. Idiomatic expressions other than sayings may also be based on metaphor, and they may also be given specific twists, in what Anita Naciscione has called 'instantial stylistic use.' Here is her example with *the course of true love never did run smooth*, from D. H. Lawrence's story *Mr Noon*:

> The course of true love is said never to run true. But never did the course of any love run so jagged as that of Joanna and Mr. Noon. The wonder is, it ever got there at all. And yet, perhaps, a jagged, twisty, waterfally, harassed stream is the most fascinating to follow [Naciscione, 2001: 74].

Another stylistic exploitation of specific metaphors involves allusion and intertextuality. A well-known example involves the title of William Faulkner's novel *The sound and the fury,* which harks back to Shakespeare's *Macbeth*:

> Life's but a walking shadow, a poor player
> That struts and frets his hour upon the stage
> And then is heard no more. It is a tale
> Told by an idiot, full of sound and fury,
> Signifying nothing [Act 5, scene 5, lines 19–28].

Faulkner's allusion to these lines in the title of his novel is immediately relevant to the interpretation of the first part of the novel, which presents a story told by a mentally retarded man. Shakespeare's famous metaphor is one version of a series of metonymically related metaphors that are all highly conventional, including *life is a play*, *life is a player*, and *life is a stage*. Consider Shakespeare's contemporary, Sir Walter Raleigh:

> What is our life? A play of passion,
> Our mirth the musicke of division,
> Our mothers wombs the tyring houses be,
> Where we are drest for this short Comedy,
> Heaven the Judicious sharpe specatator is,

> That sits and markes still who doth act amisse,
> Our graves that hide us from the searching Sun,
> Are like drawne curtaynes when the play is done,
> Thus march we playing to our latest rest,
> Onely we dye in earnest, that's no Jest [Raleigh, *What is our life* (1612)].

The metaphor underlying Raleigh's poem is metonymically related to the more famous one produced by Shakespeare, and both may be seen as variations on a conventional theme in the Renaissance. This points to a cultural basis of metaphorical themes and their conventional and stylistically charged expression.

The complicated relation between conventional metaphor from previous periods and present-day allusion and intertextuality may be demonstrated with reference to the 20th-century song by Elvis Presley, *Are you lonesome tonight?* There is a parlando part in the song that begins "Someone said that life is a stage," and then continues by telling a sad love story that is divided into acts, and ends with an empty stage. The question arises whether Elvis has picked up on Raleigh, or Shakespeare, or on some other, intermediary source; or whether *life is a stage* has become part of the folklore of the English-language speech community. That this is not an isolated coincidence is shown by the possibility of a comparable relation between Shakespeare's famous *Juliet is the sun* and the following line from a hit song by British rock band, The Cream: "you're the sun, and as you shine on me, I feel free."

Even more complex possibilities for intertextual stylistic play are suggested by potential allusions to the cognitive-linguistic or metaphorological literature. Thus, Julian Barnes, in his novel *Metroland,* had a chapter called 'Sex is travel,' which comes suspiciously close to LOVE IS A JOURNEY, the favorite example from Lakoff and Johnson's *Metaphors we live by*, which was published in the same year, 1980. The content of Barnes's chapter, however, reveals that this idea can also be interpreted as metonymic rather than metaphoric, in that sex is not similar to a journey but requires travel to the beloved.

Another, similarly innovative stylistic exploitation of a metaphor familiar from the theoretical literature is offered by Michel Faber, in his fantasy/science-fiction novel *Under the skin*. One of the characters utters the following words: "A butcher has to be a bit of a surgeon you know." This is a deliberate perversion of the directionality of a metaphor that has received a lot of attention, *this surgeon is a butcher.* However, its perversion is extremely functional in the situational context of the novel, in which people are treated like cattle and are fed and slaughtered for future consumption by a group of aliens – alien butchers of humans having indeed to be something like surgeons.

These phenomena can all be seen as forms of uptake of a specific metaphor by another language user. This may also occur in more direct and reciprocal forms of discourse, such as ongoing conversations. Interlocutors may take up metaphors on the spot, as it were, for purposes of acceptance or rejection, extension, and development, and for sincere, as opposed to perverse, exploitation. Cameron (2003), for instance, shows how students can immediately repeat and extend metaphors offered by teachers during oral expositions in classrooms.

Metaphorical Patterns

Moving away from the stylistic importance of metaphor for specific utterances, there are also more general patterns of metaphorical style, which may relate to the style of an individual language user. A number of examples may be given from the domain of literature (see Steen and Gibbs, 2004). For instance, Elena Semino has shown how the metaphorical aspects of the mind styles of two fictional characters, Bromden in Ken Kesey's *One flew over the cuckoo's nest* and Clegg in John Fowles's *The collector,* display different properties: Bromden's language uses conventional metaphor in creative ways, whereas Clegg's metaphorical language contains many idiosyncratic metaphors. Another area would be the style of a fictional narrator, such as the narrator of George Orwell's *Nineteen eighty-four*, studied by Anne-Marie Simon-Vandenbergen; the narrator uses animal, physical force, and liquid metaphors to express the lack of consciousness and liberty in a totalitarian world. Metaphorical style may also pertain to the language use of an entire work, as has been shown by Don Freeman for a number of Shakespearian plays. This suggests that the personal style of the complete works of individual authors may display specific patterns of metaphorical usage, as may be the case for heavily metaphorical writers such as Salman Rushdie, as opposed to authors who are clearly much less metaphorical, such as Ernest Hemingway. It will be self-evident that such patterns may also be found in the language of nonliterary writers or speakers, such as famous philosophers or politicians (e.g., Jäkel, 1997; Charteris-Black, 2004), but these have received much less attention.

Style can also be regarded as the language typically used for a particular class of discourse, as opposed to an individual's imprint on the structures of their language use. One of the most famous cases involving metaphor is the one of metaphysical lyrical poetry, which is characterized by the use of daring metaphorical conceits. These are identified by their

combination of a specific form, in that they are often presented as analogies or even full-blown arguments, with a particular content, which seems to force the difference between the two domains on the reader more than their fragile and often strained similarity. Here is an example from John Donne, in his poem to Mr Rowland Woodward:

> Like one who'in her third widowhood doth professe
> Her selfe a Nunne, tyed to retirednesse,
> So'affects my Muse, now, a chaste fallownesse [Donne, *To Mr Rowland Woodward* (~1635)].

It should be noted how some stylisticians might actually object to calling these lines a metaphor, since they have the form of an analogy that may also be classified as an extended nonliteral comparison. However, the presence of an underlying cross-domain mapping cannot be contested, so that these lines do count as metaphorical in the conceptual sense of the word.

A similarly famous case is constituted by imagist poetry, wherein almost arbitrary external resemblance between entities motivates metaphorical projection from source to target domain. One of the most famous examples is the following poem by Ezra Pound:

> The apparition of these faces in the crowd:
> Petals on a wet, black bough [Pound, *In a station of the metro* (1913)].

Here, too, questions may arise about the rhetorical classification of the form as a metaphor; however, its conceptual status as a cross-domain mapping is again beyond doubt.

There are also subgenres of the novel that contain characteristically specific manifestations of metaphor in their style. Hardboiled detectives, for instance, typically contain a macho private investigator who revels in producing roughshod analogies portraying women, or more generally their view of emotional situations. Philip Kerr's *Berlin noir* trilogy provides a goldmine of metaphors, such as in the following example:

> Impatient of her, I snatched her knickers down, pulling her onto the bed, where I prised her sleek, tanned thighs apart like an excited scholar opening a priceless book. For quite a while I pored over the text, turning the pages with my fingers and feasting my eyes on what I had never dreamed of possessing [Kerr, *Berlin noir* (1994)].

More generally, David Lodge, following a suggestion made by Roman Jakobson, argued that novels are characterized by the use of simile whereas poetry displays a preference for metaphor (Lodge, 1977).

Poetry and novels are just two genres that display specific patterns of use of particular classes of metaphor. Jakobson and Lodge have postulated many more relationships, and a beginning has been made with the study of the variation of metaphor across registers and domains of discourse. For instance, Kurt Feyaerts has edited a collection of articles on the relation between metaphor and the Bible (Feyaerts, 2003), Lakoff and Johnson's latest work surveys the role of metaphor in philosophy (Lakoff and Johnson, 1999), Reuven Tsur (1987) and Gerard Steen (1994) have addressed the position of metaphor in literature (cf. Steen and Gibbs, 2004), and Lynne Cameron (2003) has examined the use of metaphor in classroom discourse at primary-school age. In the collection on metaphor and thought by Ortony (1993), there is a special section on metaphor in education and another section on metaphor in science, with contributions from Thomas Kuhn and Richard Boyd, among others. Andrew Goatly (1997) has made a beginning with describing some of these relations in stylistic detail, including the distribution of diverging metaphor forms across conversations, news reports, popular science, magazine advertisements, novels, and lyric poems.

Finally, the broadest scope for a stylistic approach to metaphor may define 'style' as the overall impression of a particular language, in contrast with another language. Thus, British English and American English have different patterns of metaphorical usage, one striking feature involving the combination between metaphor and hyperbole in American English (cf. Kövecses, 2004), as may be demonstrated with reference to the frequent exaggerated use in American English of verbs such as *die* and *kill* for many mundane actions, including the light and computers. Different languages can also utilize source domains for particular target domains in very different ways. Variation of metaphor within and between languages is turning into a new area of interest for linguists and stylisticians alike (Kövecses, 2004).

Metaphors in English, French, and Spanish Medical Written Discourse

L Divasson and I León, University of La Laguna, Tenerife, Spain

Introduction

According to the *Concise Oxford dictionary of current English*, the term *metaphor* comes from the Greek *metaphora* and signifies 'transfer, transposition' (*meta* means 'with' or 'after,' and *phero* means 'bear' or 'carry'). Aristotle in his *Poetics* viewed metaphor as part of rhetoric and poetics. To him, it consists of naming an entity with a word pertaining to something different.

There is a significant amount of research in the field. Shibles (1971) and Van Noppen *et al*. (1985) collected the publications on metaphor. The former, an annotated bibliography and history, includes more than 3000 references, and the latter provides over 4000 titles. The increased interest in metaphor studies, particularly during the 1970s and 1980s, was due to the development of cognitive linguistics.

Metaphors are linguistic devices in both fictional and nonfictional texts, whether spoken or written. The fictional writer uses them to convey certain feelings and emotions to the prospective reader and to add originality to his writing, whereas the nonfictional writer uses metaphors in order to give names to new concepts, phenomena, or discoveries and to formulate new hypotheses. Literary metaphors are considered to be richer if they can be interpreted differently by different people, whereas scientific metaphors necessarily must convey a single precise concept.

Different Approaches to Metaphor Theory

Martín-Municio (1992) offered some of the definitions of metaphor by distinguished authors, such as Cicero, De Vendôme, Nebrija, Whately, Werner, and Dámaso Alonso, which have followed that of Aristotle through the ages. All of these definitions are based on a substitute approach, i.e., on the substitution of literal expressions for metaphorical equivalences. The comparative approach, on the other hand, sees metaphor as a condensed or elliptical simile. To some scholars, metaphor differs from simile only in the form, the latter being an explicit comparison signaled by the words 'like' or 'as.' However, the distinction is not simple and it has been a cause of discussion ever since Aristotle, who mentioned the word 'enigma' to refer to this trope because there is some kind of difficulty in its nature and meaning. In past decades, the Aristotelian concept of metaphor has been reexamined and the relevance of the distinction between metaphor and simile has been questioned.

Contemporary metaphor theory can be traced back to the American philosopher Black (1955, 1962), whose works, together with those of Richards (1936) and Ortony (1993), *inter alii*, represent the nonconstructivist approach to the study of this figure of speech (*see* **Metaphor: Philosophical Theories**). They analyze metaphors at the sentence level, as independent items, and consider them nonliteral language. In an article entitled 'Metaphor,' Black (1955) introduced the concept of 'assumptive frameworks' or systems of associated common places, to describe how dissonant statements can be explained and shared with others by means of metaphors. In *Models and metaphors* (1962), he exemplified the meaning of these tropes with a short series of expressions, such as the well-known metaphor: *Man is a wolf* (see English, 1998). He also coined the terms Focus and Frame. The former is the word bearing the metaphorical meaning and the latter is the remainder of the sentence where the word occurs. Richards (1936) was the first to use the terms Topic (or Tenor) and Vehicle of the basic structure of metaphor. This terminology is widely spread. Topic is the entity we are referring to and Vehicle is that with which we compare it. The common features constitute the foundation of the metaphor. A frequently cited example is 'muscle' (from the Latin word *musculus*, which means 'small mouse'). In this metaphor, 'muscle' is the Topic, 'small mouse' is the Vehicle, and the basis of the transfer rises from the real (or imaginary) resemblance between the small mouse and the muscle on the dissection table.

The constructivist approach can be found, among others, in Reddy (1979) and, particularly, Lakoff and Johnson (1980) and Lakoff (1992). They discarded the distinction between literal and nonliteral language and considered metaphors as phenomena of both language and thought. Lakoff and Johnson, in their famous book *Metaphors we live by*, have demonstrated how much of our conceptual system is of a metaphorical nature and how our vision of reality is manifested by the use of conventional metaphors and the creation of new ones.

With regard to current studies on metaphor in the field of applied linguistics, several tendencies have been clearly identified (see Skorcynska, 2001): the first is concerned with re-establishing a language focus in metaphor research without discarding the value of the cognitive approach; the second relates

to the increase in the number of studies where metaphor is analyzed in specialist domains. Finally, there is also a marked interest in establishing a taxonomy of description levels in the methodology employed in this field of research.

Metaphor and the Creation of Language

One of the functions of metaphor is to provide a new scientific terminology, adjusting the language to new knowledge (*see* **Metaphor and Conceptual Blending**). An essential characteristic of this figure of speech is to

Table 1 Metaphors in English, French, and Spanish medical prose that refer to anatomical forms and structures

serve as a cognitive mechanism to understand abstract concepts through common notions. The metaphorized word will have a precise meaning within a scientific field. Competing with other processes (morphological, syntactic, lexical, or stylistic), metaphor has largely contributed to enrich the language of science.

The creative power that metaphor has given to language has been stressed ever since Aristotle. In the words of Skoda, in her book *Medecine ancienne et métaphore* (1988: IX):

> *La création d'un vocabulaire scientifique est un phénomène linguistique passionnant. Témoin des origines et du développement d'une science, ce procès de dénomination se trouve indissolublement lié à la naissance et aux progrès de la pensée scientifique.*
>
> *... La métaphore ... est aussi ce qui donne vie aux lexiques spécialisés, techniques et scientifiques.*
>
> [The generation of a scientific vocabulary is a fascinating linguistic phenomenon. Having born witness to the origins and development of a science, this coinage process is found to have indissoluble ties to the beginning and progress of scientific thought.
>
> ... Metaphor ... also gives life to technical and scientific specialized lexicons.]

Classification of Medical Metaphors

Two major works have been carried out on medical metaphors. The first is Skoda's study that we referred to above. It is a philological and linguistic study of the metaphorical creation in anatomical and pathological terminology of ancient Greek. The author gathers and compares the medical metaphors in ancient and modern languages and shows metaphorical matrices in the terminology of both ancient and modern medicine. The second is Salager-Meyer's research paper (1990) on the patterns of analogy underlying medical metaphors in English, French, and Spanish.

Among the countless metaphors created by humans (see Martín-Municio, 1992), there is a certain variety of conceptual domains, which can be found in many different languages and styles and which have given rise to the following types of metaphor: anthropomorphic, zoomorphic, phytomorphic, architectural, and to a lesser extent, mythological, biblical, related to food, etc. The above-mentioned studies by Skoda and Salager-Meyer have identified similar semantic subgroups, all based on patterns of analogy. These patterns of analogy can be found in both anatomical and pathological descriptions.

Table 1 depicts examples of current medical metaphors in English, French, and Spanish that express a unitary concept in a condensed univocal way. They also show how metaphoric transfer moves from specific, familiar surroundings to less known or abstract domains. They have been taken from the revised works as well as *Elsevier's medical dictionary. English/American. French. Italian. Spanish. German* (1975) and *Stedman's (illustrated) medical dictionary* (1990).

Pathology and morbid anatomy are also a source of metaphorical creation (Skoda, 1988). Many diseases, deformities, disturbances, fractures, etc., are described as well in terms of the reality surrounding us (architecture, nature, house, objects, etc.) with which they bear some resemblance, either in shape or in some other aspect (see Table 2).

A number of *martial* metaphors have also been identified in the language of medicine, as if the immune system, for instance, were '*at war*' with bacteria and viruses, and the body had turned into a '*battlefield*.' It has 'to *fight* and *resist* infections,' 'to *attack* and *destroy* cancer cells.' There are 'blood–brain *barriers*,' '*exploratory* tests and surgery,' 'cough *maneuvers*,' '*defense* mechanisms,' 'heart *attacks*,' 'tubal *blocks*,' '*invasive* carcinomas.' A '*savage* therapy' may become necessary and procedures can be '*aggressive*' or '*invasive*.' Reflexes are '*triggered*,' 'volunteers are *recruited*,' 'patients are *enrolled* in studies,' etc.

Apart from Greek and Latin, many other languages, such as Standard Arabic (Arabic), Scandinavian, Spanish, Italian, Standard German (German), and Japanese, have contributed words to the vocabularies of the life sciences in English. French terms are more numerous than those from any other modern language. The following French metaphorical expressions appear unchanged in current medical English, whereas they are translated into Spanish in the medical literature written in this language: *sonde coudée* ('elbowed line'); *bruit de diable* ('venous hum');

Table 3 Literary, mythological, and biblical metaphors in English medical prose

Lear complex	(After a Shakespearean character)
Münchhausen syndrome	(After the protagonist of *The Adventures of Baron Münchhausen*)
Pickwick syndrome	(After a Dickens's character)
Mons *veneris*/ venereal diseases	(Have a Latin root in *Venus*, goddess of love)
Oedipus/Electra complex	(Mythological characters)
Collar of *Vulcanus*	(Mythological character)
Hermaphroditism	(After *Hermaphrodite*, son of Hermes and Aphrodite)
Morphine	(Has a Latin root in *Morpheus*, god of dreams)
Cain's complex	(Biblical character)
Diogenes's cup	(Biblical character)

Table 4 Lexicalized metaphors in English, French, and Spanish medical prose

English	*French*	*Spanish*
Clavicle ('a small key')	*Clavicule*	*Clavícula*
Ventricle ('small belly')	*Ventricule*	*Ventrículo*
Pylorus ('a gatekeeper')	*Pylore*	*Píloro*
Alveolus ('a through')	*Alvéole*	*Alvéolo*
Placenta ('a cake')	*Placenta*	*Placenta*
Jejunum ('that does not eat')	*Jejunum*	*Yeyuno*
Placebo ('I will please')	*Placebo*	*Placebo*
Thyroid ('a shield')	*Thyroïde*	*Tiroides*

cancer en cuirasse ('resembling a cuirass'); *placenta truffée* ('as if stuffed with truffles'); *cri-du-chat syndrome* ('cat's cry syndrome'); *bruit de cuir neuf* ('resembling new leather sound'); *bruit de scie* ('sawing sound'); *bruit de clapotement* ('splashing sound'); *la belle indifférence* ('an inappropriate lack of emotions').

Medical science has also drawn metaphorical references from literature, mythology, and the Bible, to name certain diseases and certain parts of human anatomy (see Table 3). These literary, mythological, and biblical metaphors can be found in French and Spanish as well.

The original figurativeness of certain expressions has nonetheless faded away in the course of time and use (see Sutton, 1993) and what we take to be literal terms of scientific description are in fact the remains of figures of speech that have become too familiar to maintain their metaphorical value, as seen in the words referred to as lexicalized or dormant metaphors shown in Table 4.

Most of the above metaphorically used words belong to the nominal group and, to a much lesser extent, to the adjectival and verbal groups. (See Salager-Meyer's (1990) study, which offers a quantitative and qualitative analysis of medical metaphors and their linguistic features in English, French, and Spanish.)

Scientific and technical lexis would certainly be poorer without the use of some metaphorical expressions. Medical vocabulary, the reviewed studies show, is not devoid of picturesque metaphorical descriptions. Some examples are as follows: in English, *hot potato voice; Mexican hat cell; anchovy sauce pus*; in French, *fissuration en anse de seau* ('bucket-handle fracture'); *muguet des nouveau-nés* ('mouth candidiasis'); *aspect de ciel étoilé* ('starry sky aspect'); and in Spanish, *meato en hocico de pescado* ('fish-mouth meatus'); *soplo en rueda de molino* ('mill wheel murmur'); *angioma del picotazo de cigüeña* ('stork bite angioma').

As so aptly stated by Salager-Meyer, few expressions are, nonetheless, as colorful as that registered in the French corpus she analyzed: "*la moisson de descellement cotyloidien va être florissante*" [the cropping of cotyledons will be exuberant].

Thus, metaphors, far from being a feature of poetry and rhetoric alone, show that they have, within specialized texts and particularly within medical literature, great capacity to use lexis not belonging to the field in question. As seen in the works of Skoda and Salager-Meyer, they play an important role in medical nomenclature.

Metaphors in Political Discourse

P Chilton, University of East Anglia, Norwich, UK

© 2006 Elsevier Ltd. All rights reserved.

Everyone knows that politicians use language in ways designed to persuade, and perhaps deceive, and some people would include 'metaphors' as examples of political rhetoric. It is important to be clear what is understood by the term 'metaphor.' In the first part of this article we outline the traditional understanding and then the contemporary cognitive theory of metaphor. In the second part we apply the latter to examples of political discourse, specifically discourse about political institutions, showing how a scientific understanding of metaphor can yield insights into what humans are doing when they reason about politics.

The Classical Tradition

Greek and Roman thinkers were well aware that language was integral with politics and public life in general and studied it under the rubric of 'rhetoric.' Their writings on the subject to some extent seek to explain metaphor (among many other rhetorical devices) as a phenomenon of human communicative behavior, but they were far more concerned with evaluating the persuasive or esthetic effects of metaphors with a view to advising public speakers.

Aristotle, however, has a theoretical framework. He defines metaphor as 'the application of a word that belongs to another thing' (Aristotle, 1995: 21) and discerns different types of such application. For Aristotle, then, metaphor is about the use of words, not about the nature of thought. Moreover, Aristotle thought of metaphor as something exceptional. In *Rhetoric* he is above all concerned with the emotive effects caused by metaphor and by the 'correct' choice of metaphors. He regards metaphor as special to certain forms of writing and speaking and to certain talented individuals. These ideas, repeated by classical writers such as Cicero and Quintilian, are implausible in the light of modern research on metaphor. Aristotle does note the role of metaphor in the expressing of new ideas, but others concentrated on functions such as being brief, and avoiding obscenity and eulogistic embellishment. In fact, the tendency is to reduce the prominence of metaphor and to handle it with a fair degree of suspicion.

This stance is inherited and magnified by the early modern philosopher and pivotal political theorist Thomas Hobbes (cf. Chilton, 1996). Here is Hobbes on metaphor: "Metaphors, and senseless and ambiguous words, are like *ignes fatui*; and reasoning upon them, is wandering amongst innumerable absurdities; and their end, contention, and sedition, or contempt" (*Leviathan*, chapter 5, pp. 116–7, original emphasis). In this passage it becomes clear that for Hobbes metaphor may actually be a kind of threat to the political status quo. This should at least alert us to the possibility that metaphors play a very important role in political life.

The Cognitive Theory of Metaphor

In the 1980s linguists realized that metaphor was not simply a matter of transferring a word from its 'proper' referent to some other referent, nor a special use of language confined to the literary or oratorical domains (cf. Lakoff and Johnson, 1980, 1999). The following points are essential for any serious investigation of 'metaphor in political discourse.'

First, metaphor is a cognitive, not a linguistic phenomenon. The human mind has various forms of organized knowledge. These may be innate or partly innate and elaborated by culture-relative experience. Let us call these 'domains.' Metaphor is then defined as a mapping from a source domain of this type to a target domain. The evidence suggests that many source domains tend to be based in physical, especially spatial, experience and be stored in the mind as what are often referred to as 'image schemas.' What the

Everyone knows that politicians use language in ways designed to persuade, and perhaps deceive, and some people would include 'metaphors' as examples of political rhetoric. It is important to be clear what is understood by the term 'metaphor.' In the first part of this article we outline the traditional understanding and then the contemporary cognitive theory of metaphor. In the second part we apply the latter to examples of political discourse, specifically discourse about political institutions, showing how a scientific understanding of metaphor can yield insights into what humans are doing when they reason about politics.

The Classical Tradition

Greek and Roman thinkers were well aware that language was integral with politics and public life in general and studied it under the rubric of 'rhetoric.' Their writings on the subject to some extent seek to explain metaphor (among many other rhetorical devices) as a phenomenon of human communicative behavior, but they were far more concerned with evaluating the persuasive or esthetic effects of metaphors with a view to advising public speakers.

Aristotle, however, has a theoretical framework. He defines metaphor as 'the application of a word that belongs to another thing' (Aristotle, 1995: 21) and discerns different types of such application. For Aristotle, then, metaphor is about the use of words, not about the nature of thought. Moreover, Aristotle thought of metaphor as something exceptional. In *Rhetoric* he is above all concerned with the emotive effects caused by metaphor and by the 'correct' choice of metaphors. He regards metaphor as special to certain forms of writing and speaking and to certain talented individuals. These ideas, repeated by classical writers such as Cicero and Quintilian, are implausible in the light of modern research on metaphor. Aristotle does note the role of metaphor in the expressing of new ideas, but others concentrated on functions such as being brief, and avoiding obscenity and eulogistic embellishment. In fact, the tendency is to reduce the prominence of metaphor and to handle it with a fair degree of suspicion.

This stance is inherited and magnified by the early modern philosopher and pivotal political theorist Thomas Hobbes (cf. Chilton, 1996). Here is Hobbes on metaphor: "Metaphors, and senseless and ambiguous words, are like *ignes fatui*; and reasoning upon them, is wandering amongst innumerable absurdities; and their end, contention, and sedition, or contempt" (*Leviathan*, chapter 5, pp. 116–7, original emphasis). In this passage it becomes clear that for Hobbes metaphor may actually be a kind of threat to the political status quo. This should at least alert us to the possibility that metaphors play a very important role in political life.

The Cognitive Theory of Metaphor

In the 1980s linguists realized that metaphor was not simply a matter of transferring a word from its 'proper' referent to some other referent, nor a special use of language confined to the literary or oratorical domains (cf. Lakoff and Johnson, 1980, 1999). The following points are essential for any serious investigation of 'metaphor in political discourse.'

First, metaphor is a cognitive, not a linguistic phenomenon. The human mind has various forms of organized knowledge. These may be innate or partly innate and elaborated by culture-relative experience. Let us call these 'domains.' Metaphor is then defined as a mapping from a source domain of this type to a target domain. The evidence suggests that many source domains tend to be based in physical, especially spatial, experience and be stored in the mind as what are often referred to as 'image schemas.' What the

metaphorical mapping does is transfer structure from the source domain to a less well-specified domain.

Second, it is apparent that such metaphorical mappings account for the meanings of many ordinary words in a language as well as idiomatic expressions. Metaphors are therefore not confined to special genres. However, in political discourse, as in other types of discourse, particular words and idioms will obviously be relevant, so particular metaphors will be also. We will see that certain image schemas are an important source of political concepts, e.g., the source–path–goal schema and the container schema. An important point to be made here is that metaphors are actually an instrument for reasoning, contrary to what was asserted by Hobbes. They provide a means by which the human mind can make inferences, for if metaphors map structure from a source domain to a target domain, inferences that can be done in the source domain can (potentially) be done in the target domain.

Another methodological consideration concerns the etymology of political vocabulary. In English and some other languages many words for political phenomena derive from Latin or Greek words with different meanings. Meaning change in general is often metaphorical in the sense defined here. In the case of political words the metaphors involved can be of interest because they give some indication of how the human conceptual system operates over historical time in this domain of human life.

Finally, two caveats are in order. First, this article refers primarily to metaphor in political discourse in English. Second, it refers to the Western political tradition. Whether the points made can be generalized is a question for further research.

Metaphor and Politics

Political behavior involves using language as a form of political action and as a form of reflection on (metarepresentation of) political behavior. The two are not of course entirely separate but in what follows we shall focus on the second. What, then, are the political concepts that have a metaphorical basis?

If we make the assumption that political behavior involves both cooperation and competition, we can ask how metaphor is involved in the conceptualizing of this duo. It is clear that the relevant concepts will concern differentiation of various sorts and the relations among the parts. Relations of power will be especially significant.

The basic vocabulary of hierarchy and precedence is derived metaphorically from spatial concepts. Two of the fundamental image schemas are the front–back schema and the up–down schema, based on human anatomy, perception and cognition.

The front-back schema gives us metaphorical mappings for precedence (the word itself being etymologically metaphorical [*prae-cedere*] and related to physical ordering of individuals in procession). This is why we speak of an individual or group coming **before**, in **front** of, **ahead** of, in the **vanguard**, etc., while others **come behind**, **fall behind**, **follow**, etc. It will be noticed that these expressions contain mappings from additional image schemas. One of these is the path schema, which reflects experience of human movement. Front–back combined with path gives us the powerful concept of **leadership** and **followers**. In certain political discourses, such concepts are applied to whole groups (ethnic groups, states, regions) in expressions such as '**backward** nations'; indeed the concept of **progress** itself is etymologically derived (*pro-gressus*) from the spatial front–back and path schemas. In persuasive political discourse, orators frequently claim that their country is, or urge that it should be, **moving forward**. In fact, this schema appears to be indispensable for the meanings associated with one important strand of political discourse, namely reference to policy and future planning. Politicians and their bureaucrats thus frequently speak and write of **looking toward the future**, **taking rapid steps**, **moving on**, coming **to a crossroads**, **going in the right direction**, and so on.

In the up–down schema, **up** maps onto good, strong and powerful. Thus superior individuals or groups are not only better in some normative sense, but also possess power **over** others. These expressions are embedded in the language and enter into systematic semantic relations. Thus if someone is **over** or **above** you, you are **beneath** or **below** them; you will be **subordinate**, **inferior**, and they may **stoop**, **condescend**, and so on. This network is the basis for further concepts: a group may **rise up**, or cause an **uprising**, and an established authority may **decline**, **fall**, or **collapse**. The basic image schema of standing upright is important to the rather complex development of the concepts evoked by words such as 'estate' and 'state.'

Concepts of control and power are lexically encoded by way of the spatial up–down image schema. This can be seen from the constructions into which the relevant lexical items enter in English and other languages. For example, it is systematically the case that we say power **over**, control **over**, authority **over**, charge **over**, responsibility **over**, and so forth, rather than some other preposition. One of the key concepts of Western political philosophy from the early modern period onward is **sovereignty**. The history of this word, like that of the term 'state,' is complex, but what should be noted here is that it is also metaphorically derived according to the

up–down schema: *sovereign* > popular Latin *superanus* > Latin *super* ('on top of,' 'over').

The conceptualization of discrete groups of individuals, in many cases in discrete geographical regions, is probably a crucial component of political thinking and action. The form of such concepts is provided by the basic container image schema, which has many politically significant ramifications. The container schema captures human experience of 'inside,' 'outside' and the intermediate boundary. On the linguistic evidence, it is apparently recruited by the conceptual system to understand, reason about, and communicate about social groups. In reality collections of objects and individuals need not have determinate bounds. The container image schema, however, imposes them. Presumably it coincides with what may or may not be a basic schema, that of self and other. It is this schema that makes it possible to draw inferences such as: if A is not **in** the group, then he is **outside** it; in order to **enter** the group A must cross a boundary. As Chilton (1996) and Chilton and Lakoff (1995) argued, the container schema is fundamental to the concept and discourse of security, as well as to the modern concept of the state and the international system, where countries and regions are conceptualized as container-like entities. Two combinations with other image schemas are worth noting here. In combination with the center–periphery schema, we have political concepts of **central authority** and **remote** or **peripheral regions**. In combination with the path schema, we have what appear to be emotionally charged concepts of invasion, incursion, and the infringement of national boundaries.

In the Western political tradition certain metaphors with cultural (rather than image-schematic) sources for the state have recurred, as Peil (1983) has shown: the body politic, the ship of state, buildings, machines. The first three can be regarded as linked to the container schema, and the body schema involves basic as well as cultural knowledge. All provide rich possibilities for political inferences in the sense outlined earlier.

The body-politic metaphor is particularly entrenched. It permits the mapping of structured knowledge about the body (and its ills) onto the political domain. If the polity has a **head**, it also has its lesser parts that serve it. If the polity is a body, then it may have **disease**, which may be due to an invasive element, e.g., a **parasite**. It follows that it needs a **physician** to **cure** it, who may prescribe a **cure** such as a **purge**. As is well known, this train of thought was developed and manipulated in Nazi thinking and propaganda. Peil's other metaphors provide inferential potential that will be more or less familiar to readers. If the state is a **ship**, it may need a strong **captain** to **steer** it though **rough seas**; if it is a building it will need strong **foundations**, a **roof** to protect it, and **pillars** to hold it up; if it is a **machine**, then there are **levers** of power, the machinery has **checks** and **balances**, and it may be more or less **efficient**, or may go **out of control**.

Such examples suggest that the cognitive theory of metaphor provides a means of investigating the intricate conceptual networks that underlie discourse about political institutions. They also suggest that core features of political theory, at least in its traditional Western forms, make use of metaphors derived from a small set of image schemas. But these are hypotheses for future research.

Metaphors, Grammatical

D Rose, University of Sydney, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

Grammatical metaphor is a semiotic process first described in Halliday (1985/1994). It is a set of strategies for expanding the range of meanings available to speakers and writers that involves transference of a semantic function from the grammatical class that most typically realizes it to a class that typically realizes a different type of meaning. Halliday suggested that grammatical metaphor is a feature of all adult discourse. This may hold for all languages as well, because it is found in languages as diverse as English and Indigenous Australian languages. However, certain types of grammatical metaphor have become a major feature of written discourse in modern institutions, such as science, academia, and bureaucracy (Halliday and Martin, 1993; Martin and Veel, 1998), and present a serious challenge for many learners.

Halliday (1994: 340–341) first discussed three familiar types of 'rhetorical transference': 'metaphor,' in which a "word is used for something resembling that which it usually refers to"; 'metonymy,' in which a "word is used for something related to that which it usually refers to"; and 'synecdoche,' in which a "word is used for some larger whole of which that which it refers to is a part." Halliday gave the following examples of these types of transference:

metaphor	A flood of protests poured in	[*flood* exemplifies *a large quantity*]
metonymy	Keep your eye on the ball	[*eye* directs the *gaze*]
synecdoche	Let's go and have a bite	[*a bite* is part of eating *a meal*]

The term metaphor is also used as a general label for these types of verbal transference. A common view of metaphor is a transference in the usage of words. However, Halliday proposed that we look at it first from the perspective of meaning and ask "not 'how is this word used?' but 'how is this meaning expressed?'" This perspective derives from the systemic functional model of language (SFL) as stratified into three levels – of meaning, which is expressed as wording, which is expressed as sounding or lettering. More technically, discourse semantics is realized as lexicogrammar, which is realized as phonology (where the level of wording includes lexis and grammar as a unified system). This stratal model of language is diagrammed in Figure 1.

This approach privileges discourse semantic functions as a starting point for analysis of grammatical patterns rather than merely the forms of words and sentences. Therefore, from a perspective 'below,' of lexis alone, *flood* literally means 'a moving mass of water' and can be used metaphorically as 'a moving mass of feeling or rhetoric'; however, from the perspective 'above,' of discourse semantics, the meaning 'many people [protested]' may be expressed more congruently as *a large number* [of protests] or more metaphorically as *a flood* [of protests].

Here, Halliday introduced the term 'congruent' in place of 'literal' to denote a less metaphorical variant. Semantically speaking, *a large number* is a more congruent expression of the meaning 'many,' whereas *a flood* is a more metaphorical expression. This supposes a model of congruence between meaning and wording that lies at the heart of systemic functional theory (i.e., that certain types of wording have evolved to realize certain types of meaning). For example, the nominal group *many people* realizes the general semantic categories of 'person' and 'quantity,' whereas the verb *protested* realizes the semantic category 'process.' More specifically, 'person' is realized by the noun *people* and 'quantity' by the adjective *many*. These are all examples of congruence between meaning and wording: 'people' and 'things' realized as nouns, 'qualities' and 'quantities' as adjectives, and 'processes' as verbs.

There is a sense in which congruent expressions are prior to metaphorical ones on two timescales: the evolution of the language, or 'phylogenesis,' and the development of the speaker, or 'ontogenesis.' Not only in English but also probably in the spoken modes of all languages, the semantic configuration 'person' + 'quantity' + 'process' is congruently realized by the grammatical structure of a clause consisting, for example, of a nominal group with noun and

Figure 1 Stratal model of language.

adjective *many people* and a verb or verbal group *protested*. In terms of phylogenesis, this is a pattern that evolved initially in the spoken mode and appears to be common across languages and registers, whereas metaphorical variants have evolved more recently and may vary widely within and between languages. For example, the meaning 'quantity' may now be realized by a nominal group such as *a large number*, and the meaning 'process' may be realized by a noun such as *protests*. In a further step, the semantic figure 'person' + 'quantity' + 'process' can then be realized as a single nominal group *a large number of protests*, in which the people doing the protesting have disappeared. This metaphorical 'thing' can then participate in another process, such as *a large number of protests came in*.

Such a reconstrual of 'person' + 'quantity' + 'process' as though it were 'quantity' + 'thing' forms the semantic basis for the more metaphorical expression *A flood of protests poured in*, which has the effect of intensifying the quantity by means of the lexical items *flood* + *poured*. The metaphor is thus both lexical and grammatical: A semantic configuration that is more congruently realized by a clause structure *many people protested* is realized more metaphorically by a nominal group *a large number of protests*, and its elements that are more congruently realized by one lexical item *a large number* are realized more metaphorically by another lexical item *a flood*.

For several reasons, these kinds of metaphorical expression have evolved in recent centuries in the written mode of languages such as English, where they are now common. In particular, they open up the potential for expanding meanings available to writers and speakers, and they enable us to more flexibly manipulate the structures of written discourse. They are less often found in the languages of more stable cultures that have not evolved a written mode, such as Indigenous Australian languages (Rose, 2001). This does not imply any valuing of written over oral cultures, but it is a very important point to recognize for both cultural studies and language education. In the ontogenesis of English speakers, such metaphorical expressions appear as learners engage with the written mode, typically in later years of primary school (Derewianka, 2004). However, for learners from oral cultural backgrounds, they can present a major barrier for understanding and using written discourse since they reconstrue ordinary people and things acting in the world as relations between abstract entities (Martin, 1991; Rose, 1997, 1998).

On the other hand, grammatical metaphor is a feature of all adult discourse, but most commonly in its interpersonal guise. Halliday distinguished types of grammatical metaphor most generally as metaphors of 'mood' and 'modality' and metaphors of 'transitivity': the first expands the potential of language for interpersonal meanings, and the latter expands its potential for ideational meanings. These categories arise from the recognition in systemic functional theory of distinct 'metafunctions': to enact speakers' social relations (interpersonal metafunction) and to represent their experience (ideational metafunction). A third textual metafunction is to organize the interpersonal and ideational as discourse that is meaningful in context. Metafunctions are mapped on to the stratal model in Figure 2.

The following sections first outline interpersonal metaphors of mood and modality, followed by ideational metaphors of transitivity and conjunction.

Interpersonal Metaphor

Interpersonal metaphors expand the potential of a language for negotiating social relations by manipulating the congruent realizations of discourse semantic systems of exchange and appraisal. These discourse systems are realized in the grammatical systems of mood and modality, respectively.

Metaphors of Mood

Exchange systems enable speakers to demand and give either information or goods-and-services, most generally through the speech functions of question and statement (propositions) or command and offer (proposals). These speech functions are realized in the grammatical systems of mood as interrogative, declarative, or imperative clauses, exemplified in Table 1.

Thus, each of these speech functions has a congruent realization as one or another mood type. Since they frequently occur nonsemiotically by simply performing an act, offers of goods-and-services have

Figure 2 Metafunctions and language strata.

Table 1 Speech functions and mood

Speech function		*Mood*
Question	*Do you have a blanket?*	Interrogative
Statement	*I have a blanket.*	Declarative
Command	*Give me your blanket!*	Imperative

no particular congruent realization but may be verbalized by any mood type; for example, [interrogative] *Would you like my blanket?* [declarative] *Here's a blanket*, or [imperative] *Have my blanket!*

Now direct commands often imply, either an asymmetry of status in a relationship or a close relationship, and such implications may not be desirable in a relationship in which status and contact require more delicate negotiation. For these reasons, adult speakers often use metaphors of mood to negotiate such exchanges, with interrogative or declarative clauses in place of imperative; for example,

I would like a blanket.
May I have a blanket?
Would you mind if I had a blanket?
A blanket would be nice.

Such mood metaphors modulate obligation by reconstruing a demand for goods-and-services as though it were an exchange of information. They also enable obligation to be delicately graded from direct imperatives through modulated declaratives to apparently neutral statements or question, considerably expanding the potential for negotiating exchanges.

Metaphors of Modality

Halliday (1994: 354–363) described two general kinds of modality, one for negotiating services and the other for negotiating information. Demands for a service can be negotiated as follows:

do it	positive
you must do it	
you should do it	
you could do it	
don't do it	negative

On this scale we can say 'how obliged' you are to act. Statements that give information can be negotiated as follows:

it is	positive
it must be	
it should be	
it might be	
it isn't	negative

On this scale we can say ''how probable' a statement is. At each pole of these scales of modality is the choice of positive or negative polarity.

Each modality type is realized congruently in the English verbal group as modal auxiliary verbs ('must,' 'should,' 'might,' etc.) or modal adverbs ('certainly,' 'probably,' 'possibly,' etc.), but their potential is expanded by employing other regions of the language system. Modality can be made explicitly subjective using mental projections, or explicitly objective using projected facts, as follows:

Explicitly subjective

do it	positive
I insist you do it	
I want you to do it	
I'd like you to do it	
don't do it	negative

Explicitly objective

do it	positive
you are required to do it	
you are supposed to do it	
you are allowed to do it	
don't do it	negative

These metaphors of modality explicitly locate the source of obligation with the speaker (subjective) or away from the speaker (objective), opening up the potential for negotiating status and contact. This is a very large region of English grammar, which Halliday outlined and argued at length. Other languages have comparable systems of mood and modality (Caffarel *et al.*, 2004), although they may be realized in different ways. For example, the Australian language Pitjantjatjara grades degrees of obligation within the imperative mood system rather than as a separate system of modality. Nevertheless, it uses metaphors of mood and modality for similar interpersonal functions, as does English, as follows (from Rose, 2001):

Congruent command (imperative mood)
walangku watja-la
quickly tell-IMP
Quickly tell me!

Explicitly subjective (mental projection)
α ngayulu mukuri-nganyi β anku-ntjikitja
I desire-PRES go-to
I want to go.

Explicitly objective (relational clause)
nyuntu kunyu anku-ntjaku ngara-ngi
you it's.said go-to stand-PAST
You, its said, were expected to go.

Metaphors of mood are also equally common. The following dialogue begins with an interrogative metaphor for a proposal ('Give me a blanket!'). The listener reads the grammar congruently and simply answers with information (1b). He is surprised when the proposal is re-expressed as a direct imperative (2a) so that the demander offers to rephrase the request (3a):

(1a) katja // nyuntu blanketa kutjupa kanyi-ni
son you blanket another have-PRES
Son, do you have another blanket?
(1b) uwa ngari-nyi nyara
yes lie-PRES yonder
Yes, it's over there.

(2a) uwa -ni
give-IMP me
Give it to me!
(2b) munta
sorry
Sorry?

(3a) wiya nyuntu-mpa // nyanga-ngka -na
no your-s this-at I
tjapi-ni piruku
ask-PRES again
No it's yours. I'll ask this again

This exchange shows the tension in grammatical metaphor between the meaning of the grammatical structure and the discourse function it realizes metaphorically. Both levels of meaning inhere in the metaphor, and it is the tension between them that expands the meaning potential.

Ideational Metaphor

Ideational metaphors expand the potential of a language for construing experience by manipulating the congruent realizations of discourse semantic systems of ideation and conjunction. These discourse systems are realized in the grammatical systems of transitivity and complexity, respectively.

In languages throughout the world, human experience seems to be congruently construed as sequences of activities involving people and things, processes, places, times, and qualities (Caffarel *et al.*, 2004; Rose, 2004). Each activity is typically realized by the grammatical structure of a clause, and the other elements are realized by groups of words within the clause; for example (Tutu, 1999),

As an eighteen year old	I	met	a young man in his twenties
time	person	process	person

Each clause involves three kinds of elements:

1. A process
2. People and things that participate in the process
3. Circumstances that are associated with it in some way, such as time, place, manner, and so on.

We can call this arrangement of process, participants, and circumstances a 'figure' (after Halliday and Matthiessen, 1999; Martin and Rose, 2003). Figures are linked into activity sequences by conjunctive relations, which are congruently realized by conjunctions; for example,

It was the beginning of a beautiful relationship.
We even spoke about marriage.
Then one day he said he was going on a 'trip.'

Just as the grammatical class 'clause' realizes the semantic function 'figure,' so the grammatical class 'verb' is the typical expression of the semantic function 'process,' and the class 'noun' typically expresses the meaning of 'thing.' However, particularly in written modes of discourse, the meaning of 'process' is often re-expressed as a noun so that, for example, someone 'acting' becomes 'an action.' This does not simply replace one grammatical class with another but has the effect of reconstruing an everyday activity as though it were an abstract thing, thus creating two layers of meaning, as in metaphors in general. Such nominalizations are the most common type of ideational metaphor.

From the perspective of discourse semantics, ideational metaphor involves a transference of meaning from an element that congruently realizes it to another kind. For example, the process of *two people marrying* can also be treated as a quality, *a married man*, and as a thing, *a good marriage*. This kind of meaning transference seems so natural that it hardly comes to our attention, except when it becomes difficult to read in abstract written discourse, especially for readers who are unfamiliar with dense ideational metaphor. In modern written languages it is a powerful resource for expanding the set of meanings available for speakers and writers. Its development in English has accelerated during the past few centuries to enable expansion of the discourses of the sciences, humanities, and bureaucracies that accompanied Europe's industrialization and colonial expansions.

In general, the drift in meaning, by means of ideational metaphor, has been from reality as processes involving people and concrete things to reality as relations between abstract things (Halliday, 1998), as with the transference from *marrying* as process to *marriage* as thing. Part of the reason for this shift has to do with the greater potential for expanding the meaning of things – numbering, describing, classifying, and qualifying them. For example, the process of *marrying* can be expanded with another process, such as *marrying to forget*, or a quality, such as *marrying well*. However, *marriage* as a thing can be expanded with a whole series of potentially evaluative qualities, classes, and qualifiers, as in *an extremely short marriage to someone else*.

These are ideational metaphors of the experiential type (i.e., they are concerned with elements of figures). Ideational metaphors of the logical type are concerned with reconstruing a conjunction between figures as if it were a process or thing.

Experiential Metaphor

There are two general types of experiential metaphor: metaphors that reconstrue a process or quality as if it were a thing and metaphors that reconstrue a process, or a quality of a process, as if it were a quality of a thing.

Processes and Qualities as Things One major advantage of presenting other elements as entities is that things can be described, classified, and qualified in ways not available to other elements. This is illustrated in the following examples:

process ⟶	**thing**
begin	the beginning
relate	a beautiful relationship
marry	an extremely short marriage
travel	a trip
desiring	only one desire
reconcile	reconciliation
apply	all the important applications
violate	a gross violation
miscarry	a miscarriage of justice
penalize (punish)	the penalty (punishment)
expose and humiliate	public exposure and humiliation
perpetrate	the perpetrator
torturing	torturers

quality ⟶	**thing**
eighteen years old	an eighteen-year-old
twenty	his twenties
secure	security
painful and bitter	the pain and bitterness in me
true	truth
just	justice
honest/just . . .	integrity

As things, such metaphorical expressions can become participants in processes (e.g., *he had only one desire*) and parts of circumstances (e.g., *after my unsuccessful marriage*).

Processes and Their Qualities as Qualities of Things Processes and qualities of processes can be reconstrued as qualities of things.

process ⟶	**quality of thing**
securing	a top security structure
bubbling, living	a bubbly, vivacious man
envying	an enviable relationship
opening	open session
respecting	respectable members
regulate	regular torturers
quality of process ⟶	**quality of thing**
operating overseas	overseas operations
relate beautifully	a beautiful relationship
marry very briefly	an extremely short marriage
violate grossly	a gross violation
expose publicly	public exposure
torture regularly	regular torturers

Abstract Things Abstract concepts such as *amnesty* and *justice* make up institutional fields such as law, government, education, and so forth. They often refer to a large set of activities, and it may not be possible to unpack them into figures. However, some can be unpacked; for example, *a gross violation of human rights – defined as an abduction, killing, torture, or severe ill-treatment*. These are processes construed as things in order to be classified as *gross violations*. The whole figure may be unpacked as follows:

(a perpetrator) grossly violates human rights
(if he) abducts, kills, tortures, or severely ill-treats
(a victim)

In this example, a thing, *violation*, and its quality, *gross*, have been unpacked to a process, *violates*, and its quality, *grossly*, that also includes a 'perpetrator.' Also, the things *abduction, killing, torture, or severe ill-treatment* have been unpacked to actions that also include a 'victim,' as follows:

How far we go in unpacking ideational metaphor depends on our needs. For example, we could go further to analyze the abstraction *human rights*, but this would require a lot more definition.

Things and People as Parts of Activities-as-Things When processes are reconstrued as things, the people that participate in the processes are often left out, which is one reason why abstract written discourse sometimes seems so alien to our everyday experience of things going on around us. However, participants can be included when processes are reconstrued as things by presenting them as parts of activities-as-things as possessions.

Helena got married	→	Helena's marriage	→	the marriage of Helena and her lover
victims were compensated	→	victims' compensation	→	compensation for victims

In the following example, the processes of 'exposing' and 'humiliating' become things that qualify *the penalty* and are themselves qualified by their participant, *the perpetrator*:

the perpetrator	is penalized	by	publicly exposing and humiliating	him
person	**process 1**	**linker**	**process 2**	**person**

the penalty	of public exposure and humiliation	for the perpetrator
thing	**qualifier**	**qualifier**

Ideational metaphor tends to reconstrue our experience of reality as if it consisted of relations between institutional abstractions. These strategies have evolved to enable writers to generalize about social processes and to describe, classify, and evaluate them. One cost is that it may be difficult to recover who is doing what to whom; another is that this type of discourse can be very difficult to read and understand. Unpacking ideational metaphors as shown here can help to reveal how they construe reality and is one key strategy for teaching language learners how they work.

Logical Metaphor

Logical metaphor reconstrues logical relations between processes as if they were relations between elements within processes. Logical metaphor always involves experiential metaphor as well.

Conjunction as Process A common motif in abstract or technical writing is to present a consequential conjunction as a process:

such a hearing	*is likely to lead*	*to a miscarriage of justice*
participant	process	circumstance (place)

This strategy compresses a sequence of two activities into a single figure by means of experiential and logical metaphors. Experientially, the participant and circumstance represent activities ('hearing an application' and 'miscarrying justice') that are reconstrued as things (*a hearing* and *a miscarriage*). Logically, there is a relation of consequence between these activities ('if . . . then'), which is reconstrued as a process (*is likely to lead*). We can unpack such as sequence as a sequence of two figures related by conjunctions:

if such a hearing happens
then justice will be miscarried.

However, the logical metaphor of 'relation as process' incorporates more than simply consequence. First, the probability of the result is graded as ***likely*** *to lead* (in contrast to high probability *will* ***certainly lead*** or low probability *will* ***possibly*** *lead*). Second, the necessity of the consequence is also graded lexically as *lead to* (in contrast to the stronger *result in* or weaker ***associated*** with).

Therefore, one of the reasons why writers use logical metaphors for conjunctions is that they can grade their evaluation of relations between events or arguments. This is a crucial resource for reasoning in fields such as science or politics, in which it is important not to overstate causal relations until sufficient evidence has been accumulated. This function of logical metaphors is oriented to engagement of the reader.

On the other hand, logical metaphors combine with experiential metaphors to package activity sequences as manageable chunks of information. This function of logical metaphors is oriented to periodicity. For example, this figure is one step in the argument that Tutu is advancing:

The Act required that the application should be dealt with in a public hearing
unless **such a hearing was likely to lead to a miscarriage of justice**
(for instance, where witnesses were too intimidated to testify in open session).

In this sequence, a passive clause is used to start the message with *the application* and end with *a public hearing*. The *public hearing* is then the starting point for the next message (*such a hearing*), which ends with *a miscarriage of justice*. This is what is exemplified in the next step. This sequencing of information is shown as follows:

The Act required that the application should be dealt with in **a public hearing**

unless **such a hearing** was likely to lead to **a miscarriage of justice**

(**for instance,** where witnesses were too intimidated to testify in open session).

The logical metaphor (*is likely to lead*) enables the sequence of cause (*such a hearing*) and effect (*a miscarriage of justice*) to be packaged as chunks of information within a single message.

Conjunction as Circumstance Another common motif in abstract or technical writing is to present a logical relation as a circumstance:

Is	*amnesty*	*being given*	*at the cost of justice being done?*
	participant	process	circumstance (accompaniment)

The logical meaning of *at the cost of* is concessive purpose ('without'), giving the following sequence:

Is amnesty being given
without justice not being done?

Again, this strategy enables a sequence of two activities to be packaged as a single figure, with *amnesty* as one chunk of information and the circumstance as another. However, Tutu's rhetorical strategy here also includes other layers – the lexical metaphor *at the cost of* implies a balance sheet, in which income (*amnesty*) is weighed against expenditure (*justice*). So reconstruing a sequence using this metaphor adds layers of meaning to the question.

Conjunctions as Things and Qualities Conjunction can also be reconstrued as a thing or quality. The following are examples of conjunction as a thing:

conjunction ⟶	**thing**
before	the first time
then	sequel
so	reason, result, consequence
thus	conclusion
by	a means to
if	condition

The following are examples of these conjunction-as-things in discourse, and their alternative realization as a sequence:

Time
Many of those in the security forces who have come forward had previously been regarded as respectable members of their communities.
It was often **the very first time** that their communities and even sometimes their families heard . . .
Before they came forward
their communities and even sometimes their families had not heard . . .

Consequence
Conjunctions have an important role in letting us know what to expect at each step of a discourse.
This is **one reason** they tend to come at or near the start of each sentence in English.
Conjunctions let us know what to expect
so they tend to come at or near the start of each sentence in English.

Means
Amnesty didn't matter.
It was only **a means** to the truth.
The truth would come out
by amnesty being given.

Condition
The only **conditions** for gaining amnesty were:
The act for which amnesty was required should have happened between 1960 . . . and 1994
The act must have been politically motivated . . .
The applicant had to make a full disclosure . . .
The rubric of proportionality had to be observed . . .
Amnesty is gained:
if the act happened between 1960 and 1994
if the act was politically motivated
if applicant made a full disclosure
if the rubric of proportionality was observed

In each case, the logical metaphor allows other meanings to be incorporated. Logical metaphor enables 'logical things' to be numbered, described, classified, and qualified:

the **very first** time
one reason
only a means
the **only** conditions . . . 1 . . . 2 . . . 3 . . . 4

On the other hand, reconstruing conjunction as qualities means they can be used to modify things or processes:

conjunction ⟶	**quality of thing or process**
so	resulting action
by	enabling action
in fact	actual size
thus	conclusively proven
then	subsequently shown
before	previously regarded
if	conditionally approved

Here is an example of 'conjunction-as-quality':

Many of those in the security forces who have come forward had **previously been regarded** as respectable members of their communities.

This could be unpacked as follows:

Many of those in the security forces who have come forward were regarded as respectable members of their communities **before** they came forward.

How much we choose to unpack ideational metaphors in discourse analysis will depend on our purposes. We have seen two advantages of unpacking experiential and logical metaphors. One is that by paraphrasing highly metaphorical discourse in a more spoken form, we can show learners how it means what it does and also design curriculum that leads from more spoken to more written modes. Another is that we can recover participant roles and logical arguments that tend to be rendered implicit by ideational metaphor. This can be a powerful tool for critical discourse analysis, revealing implicit nuclear relations, such as agency and effect, and implicit logical relations, such as cause and effect.

Metaphysics and Language: Facts, Propositions and 'MCT Operators'

There are lots of examples of metaphysical conclusions being drawn on the basis of linguistic phenomena. Philosophers have tried to prove the metaphysical conclusion that a benevolent all-powerful God exists on the basis of claims about what 'God' means. Others have looked at tense in language and drawn conclusions about the metaphysics of time. This article presents a more technical kind of linguistically based argument, about the metaphysics of facts, propositions and modal/causal/temporal properties – an argument whose claims are especially important in the present context because of their implications for linguistic semantics.

The article is structured as follows. In this section, I first introduce two key metaphysical views: about facts and about factlike propositions. I then introduce, also in this section, some seemingly plausible hypotheses about modality, causation, and temporal order. These are the metaphysical views which will be attacked on linguistic grounds. In the next section I explain what substitutivity principles are, and survey three different kinds of substitutivity and nonsubstitutivity. Such principles clarify the linguistic phenomena that will be used to attack the metaphysical views. The first two sections essentially introduce crucial background material for the argument. In the third section, I then describe the modest means deployed in attacking the metaphysical targets: the slingshot argument. I end by noting some standard replies to this language-based argument.

I begin with facts. It seems natural enough to think of the world as not being exhausted by the objects in it. That is, to list all the objects in the world is not to say all there is to say about it: one also wants to know what properties the objects have, and what relations they stand in, etc. And to say all that, is seemingly to describe **facts**. It's also tempting to think that facts consist of complexes of ordinary, everyday objects, properties, relations, etc.; to invent a label, it is tempting to think that facts are 'world bound.' The first view that the

Metaphysics, Substitution *Salva Veritate* and the Slingshot Argument

Metaphysics and Language: Facts, Propositions and 'MCT Operators'

There are lots of examples of metaphysical conclusions being drawn on the basis of linguistic phenomena. Philosophers have tried to prove the metaphysical conclusion that a benevolent all-powerful God exists on the basis of claims about what 'God' means. Others have looked at tense in language and drawn conclusions about the metaphysics of time. This article presents a more technical kind of linguistically based argument, about the metaphysics of facts, propositions and modal/causal/temporal properties – an argument whose claims are especially important in the present context because of their implications for linguistic semantics.

The article is structured as follows. In this section, I first introduce two key metaphysical views: about facts and about factlike propositions. I then introduce, also in this section, some seemingly plausible hypotheses about modality, causation, and temporal order. These are the metaphysical views which will be attacked on linguistic grounds. In the next section I explain what substitutivity principles are, and survey three different kinds of substitutivity and nonsubstitutivity. Such principles clarify the linguistic phenomena that will be used to attack the metaphysical views. The first two sections essentially introduce crucial background material for the argument. In the third section, I then describe the modest means deployed in attacking the metaphysical targets: the slingshot argument. I end by noting some standard replies to this language-based argument.

I begin with facts. It seems natural enough to think of the world as not being exhausted by the objects in it. That is, to list all the objects in the world is not to say all there is to say about it: one also wants to know what properties the objects have, and what relations they stand in, etc. And to say all that, is seemingly to describe **facts**. It's also tempting to think that facts consist of complexes of ordinary, everyday objects, properties, relations, etc.; to invent a label, it is tempting to think that facts are 'world bound.' The first view that the

slingshot calls into question, however, is precisely that there are such world-bound facts, in the plural. Instead, the argument seeks to show that, if facts are made up of commonplace worldly things, there can be at most one 'giant' one. To be clear about the metaphysical target, it is not the very idea of facts that would have to go, for there are alternative accounts of facts which, at first glance anyway, are not threatened by the slingshot. But those accounts of facts face difficulties of their own – difficulties which world-bound facts, facts as complexes of ordinary things, are not subject to. First, as will emerge below, a rose by any other name would smell as sweet. This suggests that the fact that the rose smells sweet has the rose itself in it, not some way of linguistically describing the rose. Second, part of the point of introducing facts and the like is to see how something distinct from a sentence can serve as the sentence's meaning, hence, we can't have every linguistic change in the sentence giving rise to a different fact (or factlike thing). (Strawson, 1950 made this point early on.) Third, we want the same fact (or factlike thing) to give the meaning of sentences in different languages, which again means that a mere change in the word used ought not change the proposition denoted – otherwise 'It's raining' and 'Está lloviendo' could end up denoting different things. (I'll return to this at the end of the article.) All of these points suggest that facts are world bound. But, as we shall see, reflection upon language – and especially upon substitutivity principles – makes it hard to see how they could be.

This takes us to a related point. Positing facts often goes along with the idea that factlike things can serve as the denotations of sentences. For instance, 'Ottawa is the capital of Canada' might be taken to stand for something like the fact that Ottawa is the capital of Canada. And 'Abe Lincoln was assassinated' might be taken to denote the fact that Abe Lincoln was assassinated. Of course, it can't really be facts *per se* that are sentence denotations, because false sentences are meaningful, and they cannot stand for facts. (For example, what fact could 'Toronto is the capital of Canada' stand for, given that Toronto is not the capital? There simply is no such fact.) Still, something factlike might do the trick: sentence denotations could be taken to be propositions. But the slingshot argument, in attacking facts in the plural, equally calls into question the idea that sentences stand for factlike things: if the argument succeeds, there are no such things, facts or propositions, in the plural, that sentences could denote. Again, there can be at most one thing denoted by all true sentences. And, patently, no one thing may serve as the meaning of such diverse sentences as 'Abe Lincoln was assassinated,' 'Ottawa is the capital of Canada,' 'Russia is bigger than Uruguay,' etc.

So, one metaphysical idea is that facts are complexes built from commonplace objects, properties and relations. Another is that propositions exist independently of language, and are what sentences stand for. Each of these has been argued to fall prey to the 'slingshot.' Another metaphysical view under attack has to do with notions such as necessity, possibility, causation, and temporal order. (Call these 'MCT properties,' for modal-causal-temporal.) At first glance, it seems that whether an object has an MCT property does not depend upon what the object is called. Call this its 'first feature.' Just as the rose smells sweet under any name, the rose is **necessarily** a flower no matter what it's called; and its thorns **caused** this little cut on my hand, no matter what it's called; and it bloomed **before** July 1, no matter what it's called. MCT properties, that is, seem to be sensitive to the nature of the thing itself, not to how we speak about it. Even more obviously, just because one object has the property of being necessarily a flower, it doesn't follow that every object does. And just because something caused that cut on my hand doesn't mean that any old thing did. Similarly for temporal order: that the rose bloomed before July 1 doesn't entail that anything you wish to pick happened before July 1. Call that its 'second feature.' Curiously, the slingshot argument has been used to show that, given an added complication about logical equivalence that will be explained below, these two supposed features of MCT properties can't both apply. If we insist that not every truth is necessary, that not every event caused such-and-such, that not every event is temporally prior to so-and-so, then we must grant that whether something has an MCT property depends on what name is used for it. In this latter respect, MCT properties must be radically different from smelling sweet. (Terminological note: In what follows, I'll speak of 'operators' when I mean 'words that either modify one sentence, or connect two sentences.' Thus all of 'necessarily,' 'possibly,' 'because' and 'before' are operators in my sense. Note also that the results to be discussed do not merely apply to words that modify and connect sentences: the arguments presented could easily be extended to expressions that combine sentences with subsentences, e.g., '[$_S$ Juana died] before [$_{NP}$ the American Civil War]' combines a sentence with a noun phrase. To keep things simple, however, I will focus on operators combining or modifying sentences.)

Substitution *Salva Veritate*

I have quickly canvassed three targets of the slingshot: world-bound facts, the proposition as sentence

meaning, and the claim that MCT properties have the two features introduced just above. Eventually I will explain how technical points about substitutivity *salva veritate* – the second element in the article's title – can be used to call facts *et al.* into question. But I need to start with what substitution *salva veritate* is, the varieties of substitutional contexts (i.e., for singular terms and for sentences), constraints on such substitution, etc.

I will begin with substitutivity of singular terms. Shakespeare famously said that a rose by any other name would smell as sweet. This certainly seems right: you don't change the smell of a rose just by renaming it. We can put his point about roses less eloquently as: 'You may substitute any coreferential name for "This rose" in "This rose smells sweet" and preserve truth.' Though wordy, this also seems right, and for just the same reason: a name change doesn't yield an odor change. Nor is '—— smells sweet' an isolated example. A dog by any other name would weigh just as much, would have the same number of hairs, would have the same size ears, etc. This is substitution *salva veritate*: 'substitution while preserving truth.'

Interestingly, not all contexts are like '—— smells sweet' or '—— weighs 28lb.' Sometimes when you change the label of an object, you don't preserve the truth of the whole sentence. Consider an example adapted from W. V. O. Quine:

(1) Andre the Giant was so called because of his size

(2) André Roussimoff was so called because of his size

Sentence (1) is true: the famous wrestler adopted that name precisely because he was so big. But sentence (2) is false. Surprisingly, this is the case even though 'Andre the Giant' and 'André Roussimoff' refer to the very same person. So, unlike roses and being sweet smelling, a wrestler by any other name would not automatically be so called because of his size; if he happens to have the property of being so called because of his size under all of his names, that would be the merest coincidence.

Of course what's special and different about '—— was so called because of his size' is that it explicitly makes reference **to the name** of the person being discussed: this curious predicate applies to linguistic things, i.e., names, not (just) to the person herself. That's why you can't put in any name you like for Andre in (1): because the sentence talks about words, specifically about names. We can see this point still more clearly with quotation marks. As it happens, the city of Toronto is also known as Hog Town. These two names refer to the same place. (Toronto used to be a major center for pork processing.) Yet (3) is true, while (4) is false:

(3) 'Toronto' contains exactly three vowels

(4) 'Hog Town' contains exactly three vowels

In this case it should be no surprise that you cannot substitute coreferring names in the context '"——" contains exactly three vowels,' because this predicate is obviously about the name, not about its referent. In contrast, '—— smells sweet' does not make reference to the linguistic item employed, but is instead wholly about the flower – that's why you can substitute whatever name you like. And '—— is so called because of his size' makes reference to both the denotation and the name: it's Andre the man who is being discussed, but 'so called' makes reference to his name as well. In sum, we have contexts which don't allow substitution of coreferring names *salva veritate* (both the kind which is just about words, as in quotation mark contexts, and the kind which is about words and nonwords, as in '—— was so called'), and contexts which do allow substitution *salva veritate* (the '—— smells sweet' and '—— weighs 28lb' kind).

The excursus into substitution principles continues. I've considered one kind of thing that can be substituted, namely singular terms. And I've considered one constraint on truth-preserving substitution, namely that the predicate apply to the thing denoted, not to the words that denote. Another kind of substitution deals not with names (such as 'Andre' and 'Toronto'), but rather with sentences. In some linguistic contexts, you can preserve truth by substituting sentences that have the same truth value. This works, for instance, with 'and,' 'or,' and the other truth functional connectives familiar from classical logic. To take one example, sentence (5) is true because both of its conjuncts are true. And since (6) is true as well, sentence (7) must be true, precisely because (7) results merely from substituting the true sentence (6) in for the second conjunct of (5).

(5) Ottawa is the capital of Canada and Toronto is west of Ottawa

(6) Vancouver is west of Edmonton

(7) Ottawa is the capital of Canada and Vancouver is west of Edmonton

But many linguistic contexts don't preserve truth when one interchanges sentences that happen to have the same truth value. Take 'Just about everyone knows that ——.' Sentence (8), when embedded in this context, yields the true (9):

(8) Two plus two is four

(9) Just about everyone knows that two plus two is four

Now, sentences (6) and (8) have the same truth value: they are both true. Yet if we substitute (6) for (8), in 'Just about everyone knows that ——,' the result is (10), which is not true. Canada's geography just isn't that widely known.

(10) Just about everyone knows that Vancouver is west of Edmonton

So, unlike in the case of 'and,' we can go from the true (9) to the false (10) by substituting one true sentence for another. Thus, truth is **not** preserved under substitution, in the scope of 'Just about everyone knows that ——.' This provides an example of not being able to substitute material equivalents *salva veritate*.

One last substitution principle. There are some contexts which allow substitution of logically equivalent sentences *salva veritate*. One example is 'entails.' Any two sentences which are logically equivalent entail the same things. Thus given the truth of (11) and the logical equivalence of (12) and (13), one can derive (14) by substitution.

(11) That it's not the case that either Clinton is dead or Bush is dead entails that it's not the case that Clinton is dead

(12) It's not the case that either Clinton is dead or Bush is dead

(13) It's not the case that Clinton is dead and it's not the case that Bush is dead

(14) That it's not the case that Clinton is dead and it's not the case that Bush is dead entails that it's not the case that Clinton is dead

But not all verbs are like this. Consider words like 'know,' 'believe,' 'expect' and so on – so-called propositional attitude verbs. Not only can one not automatically substitute true-for-true sentences, while preserving the truth of the whole, one cannot even substitute a **logically equivalent** sentence while guaranteeing truth. One way to see this is to consider that there are extremely complicated, and also very simple, ways of expressing claims which are logically equivalent. Put in the simple way, a child might know that the claim is true; but put in the extremely complex way, he might not. For instance, little Billie, a five-year-old, might expect that it will snow in January. That's simple enough for a child that age. But (15) is logically equivalent to the very complex (16):

(15) It will snow in January

(16) $\{x: x = x$ & It will snow in January$\} = \{x: x = x\}$

Now, Billie might well expect the former, yet not at all expect the latter.

Since logical equivalence of sentences of the form (15) and (16) will play a key role below, let me say rather more about it. Take '$\{x: x$ is an odd number less than 27$\}$' as an example. It refers to a set – specifically, a certain set of odd numbers. For what follows, it's helpful to think of belonging to a set as involving meeting, or failing to meet, one or more conditions. For instance, an object belongs to $\{x: x$ is an odd number less than 27$\}$ if it is both an odd number, and less than 27. An object fails to belong to the set if it fails to meet either of these. Taking membership to involve meeting or failing to meet conditions, consider now the set $\{x$: Ottawa is the capital of Canada$\}$. At first glance this looks like an odd set, but the general rule still applies: an object belongs to this set if it meets the condition that Ottawa is the capital of Canada. Now, since every object meets that condition, every object belongs to that set. With this in mind, consider the first half of (16). This phrase stands for the set of xs such that x is self-identical and it will snow in January. So, there are two conditions that must be met by an object, in order for it to be in the set: the object must be self-identical, and it must be the case that it will snow in January. The first condition is trivially satisfied by every object, however. So, in a way parallel to $\{x$: Ottawa is the capital of Canada$\}$, whether an object gets into the set depends wholly upon whether it will snow in January: if it will snow in January, every object meets the two conditions for inclusion; if it will not snow in January, no object meets them. In this way, '$\{x: x = x$ & It will snow in January$\}$' comes to denote the set of all individuals, if it will snow in January. Now, the set of all individuals is also, of course, what '$\{x: x = x\}$' denotes. So the statement of their numerical identity, i.e., (16), is true if it will snow in January. On the other hand, if it won't snow in January, then '$\{x: x = x$ & It will snow in January$\}$' denotes the null set: no object satisfies the two conditions for inclusion in this set, viz., that it be self-identical and that it will snow in January. Hence, if it won't snow in January, the statement of identity between '$\{x: x = x$ & It will snow in January$\}$' and '$\{x: x = x\}$' is false: the empty set, which is what the left-hand side of the equation would denote, does not equal the set of all objects, which is what the right-hand side denotes.

In short, the two sentences (16) and 'It will snow in January' are true and false together in every circumstance. So, they are logically equivalent. Nevertheless, Little Billie, I said, may well expect that it will snow in January; but, surely, it's not the case that little Billie expects that the set whose members are such that they are self-identical and it

will snow in January is identical with the set whose members are self-identical! So, substitution of (16) for the logically equivalent (15), in the scope of 'expects that ——,' does not necessarily preserve truth. If truth is preserved, it's because of a mere coincidence, namely that the person just happens to expect both things.

So, we have sentence operators like 'and' that allow substitution *salva veritate* of merely materially equivalent sentences – i.e., of sentences which just happen to have the same truth value. And we have sentence operators like 'know' and 'expect' that don't allow that kind of substitution, and don't even allow substitution of logically equivalent sentences. This completes my explanation of substitution *salva veritate* of sentences. We also surveyed substitution of singular terms. Many contexts allow this: '—— weighs 28 lb' and '—— smells sweet.' Some do not: '—— was so called because of his size.' The next step is to put the notion of substitution *salva veritate* to work.

The Argument: The Slingshot Itself

Let's take stock. In the first section we encountered three metaphysical views. The first two involved facts and factlike propositions: that facts are made up of objects, properties, and relations, that factlike propositions exist and serve as the meanings of natural language sentences. The third involved MCT properties having two features: of applying to objects themselves, and not applying to all truths.

Given the concepts introduced above, we can now rephrase this third metaphysical view, and add a third presumption about logical equivalence:

i. Coreferential singular terms may be substituted one for another within the scope of MCT words without altering the truth of the whole sentence;
ii. Logically equivalent sentences may be substituted one for another within the scope of MCT words without altering the truth of the whole sentences.

But

iii. Sentences which are merely materially equivalent – i.e., which just happen to have the same truth value – may not be so substituted.

To introduce one last piece of terminology, this is to say that MCT words aren't hyperintensional (i.e., they meet both (i) and (ii)) but they also aren't transparent (i.e., they meet (iii)).

Before providing the language-based argument that none of these metaphysical views are really true, let's quickly recall why it matters. What is attractive about the first two metaphysical views? Why worry about giving them up? First, as stressed above, a rose by any other name would smell as sweet. Second, we can't have every linguistic change in the sentence giving rise to a different proposition. Third, and related to the second, we want the same proposition to give the meaning of sentences in different languages. And why is it attractive to say that MCT words satisfy (i)–(iii)? Well, it would seem that 'necessarily,' 'possibly,' and other modal modifiers would allow substitution fairly freely, since, as noted, they don't (seem to) apply to linguistic items. Like '—— smells sweet,' these terms seem to be entirely about things, not at all about words. It's Shakespeare's rose point once again. For example, starting with modal operators, if Andre the Giant was necessarily a human being (and it seems that he was), then André Roussimoff was necessarily a human being too: it doesn't matter what name we use for him, **he** is just as necessarily human. Similarly for causal operators: if Andre the Giant died because he had a heart attack, then André Roussimoff died because he had a heart attack. The phrase '—— died because he had a heart attack' is about the person alone, regardless of how that person is denoted. Nor, turning to the temporal 'before,' could Andre the Giant die before Clinton was president, while André Roussimoff did not. As with 'because,' 'before' just doesn't seem to work like '—— was so called because of his size' and '"——" contains exactly three vowels.' It seems to work like '—— smells sweet' and '—— weighs 28lb.' It is this kind of reasoning which supports the claim that 'necessary,' 'possibly,' 'before,' and 'because' meet condition (i): coreferring singular terms may be substituted one for another, within the scope of **these** words, without altering the truth of the whole sentence. Moreover, unlike 'know,' 'expect,' and 'believe,' logically equivalent facts are either both necessary, or both not necessary, either both possible, or both not possible, either both before a certain event, or not. Thus, MCT words meet (ii) as well. So, these operators do allow substitution of the first two kinds – they are not hyperintensional. Yet, or so it would seem, you can't substitute any old true sentence for 'Andre the Giant is human' in 'It is necessary that Andre the Giant is human': substitution of material equivalents is not sanctioned in the scope of modal modifiers. Nor can you substitute any old true sentence for 'André Roussimoff died of a heart attack' in 'André Roussimoff died of a heart attack before Clinton was president'; nor in 'Little Billie cried because André Roussimoff died of a heart attack.' So MCT words meet (iii) too. (One might sum up by saying that MCT words are a mite

promiscuous in terms of what substitutions they'll allow, but it's not a free-for-all either.)

Despite their attractiveness, however, and contrary to a once widely assumed semantics, if the slingshot argument works, MCT words either must not allow substitution of coreferring names or logically equivalent sentences, or they must allow substitution of sentences that just happen to be true together. And, despite the attractions of the metaphysical views, there can be at most one world-bound fact, and it patently cannot serve as the meaning of all sentences!

The argument, at last. As the title of this article suggests, the 'slingshot' in question is not a Y-shaped frame spanned by an elastic; it is, instead, an argument. It was dubbed 'the slingshot' by Jon Barwise and John Perry, because it "is so small, seldom encompassing more than half a page, and employs such a minimum of ammunition" (Barwise and Perry, 1981: 398). Moreover, like the eponymous Y-shaped frame, it can, despite its modest make-up, be used to attack some very significant foes.

I will present the argument in two stages. First, I will give it in the abbreviated format one often encounters in journal articles and such. Second, I will offer a more extended version of the argument.

As Barwise and Perry (1981) and Neale (1995) both note, variations on the argument, in its very brief form, seem to have been first formulated independently by Alonzo Church (1943: 299–300, 1956: 24–25) and Kurt Gödel (1944: 128–129). But I will focus on the best-known variant of the argument, that due to Donald Davidson (1967a: 19). Since his presentation of the argument is especially condensed, and has left so many readers puzzled, I will cite it in full, and then try to explain it. (NB: I have altered Davidson's numbering, and his logicomathematical notation, to bring it in line with what appears above.)

Davidson writes:

> The difficulty follows upon making two reasonable assumptions: that logically equivalent singular terms have the same reference, and that a singular term does not change its reference if a contained singular term is replaced by another with the same reference. But now suppose that '*R*' and '*S*' abbreviate any two sentences alike in truth value. Then the following four sentences have the same reference:
>
> (a) R
> (b) $\{x: x = x \ \& \ R\} = \{x: x = x\}$
> (c) $\{x: x = x \ \& \ S\} = \{x: x = x\}$
> (d) S
>
> For (a) and (b) are logically equivalent, as are (c) and (d), while (c) differs from (b) only in containing the singular term '$\{x: x = x \ \& \ S\}$' where (b) contains '$\{x: x = x \ \& \ R\}$' and these refer to the same thing if S and R are alike in truth value (Davidson, 1967a: 19).

As two generations of students can attest, this argument goes by very quickly. It is the 'slingshot' in its purest form. The first two sentences of the quotation essentially lay out, though in rather different terminology, conditions (i) and (ii) above. This is obscured by two things. First, because of the context in which he is writing, Davidson doesn't explicitly limit his claims to sentences occurring within the scope of words like 'necessarily,' 'possibly,' 'before,' and 'because.' (For a variant of the argument which is more explicitly restrictive along those lines, see Davidson, 1967b: 152–153, and also Davidson, 1969: 42.) Second, the relation between these first two sentences and conditions (i) and (ii) is obscured by the fact that Davidson is here assuming, for the sake of argument, that **sentences refer**, and hence just are a special kind of singular term; and that they refer specifically to **truth values**. Thus, when he says "a singular term does not change its reference if a contained singular term is replaced by another with the same reference," this entails (i) as a special case: the special case where the containing 'singular term' is a sentence, and the contained singular term is a name. And when he says "logically equivalent singular terms have the same reference," this yields, given his dictum about constant reference for the whole given constant reference of the parts, (ii): that logically equivalent sentences may be substituted, *salva veritate*, within larger sentences. Thus Davidson is here arguing that, despite appearances, any operator Φ, if it permits substitution of coreferential singular terms and substitution of logical equivalents within its scope, also permits substitution of sentences which are merely materially equivalent, i.e., which simply happen to share the same truth value. That is, using the terminology introduced above: if Φ is not hyperintensional, then it is transparent.

Let's now unpack this. As I reconstruct it, the slingshot argument consists of two assumptions – which together essentially say that Φ is nonhyperintensional – plus three 'lemmas' based on logical relations. The assumptions are:

A1. Substitution of **coreferential singular terms** in the scope of Φ will not change the truth value of the whole.
A2. Substitution of **logically equivalent sentences** in the scope of Φ will not change the truth value of the whole.

The first two lemmas state logical equivalences:

L1. The sentence '$\{x: x = x \ \& \ R\} = \{x: x = x\}$' is logically equivalent to 'R.'

Proof: If 'R' is true, then the left-hand side of the equation refers to the set of all individuals, because

everything is such that it is self-identical and R obtains. And that's what the right-hand side refers to as well. So, the equation as a whole is true, if 'R' itself is true. If 'R' is false, then the left-hand side of the equation refers to the empty set: if 'R' is false then nothing is such that it is self-identical and R obtains. But that's not what the right-hand side refers to: the right-hand side still refers to the set of all individuals. So, the equation as a whole is false, if 'R' is false. Thus the two sentences are logically equivalent.

L2. The sentence '$\{x\colon x = x \ \& \ S\} = \{x\colon x = x\}$' is logically equivalent to 'S.'

Proof: Same as for L1.

The third lemma establishes a coreference relation:

L3. The singular term '$\{x\colon x = x \ \& \ R\}$' is coreferential with the singular term '$\{x\colon x = x \ \& \ S\}$.'

Proof: Given that both sentences 'S' and 'R' are true, both of the singular terms in L3 refer to the set of all individuals. That is, everything is such that [it is self-identical and R]; and everything is such that [it is self-identical and S].

From the two assumptions about the nonhyperintensionality of Φ, and making use of the three lemmas about set theoretic relations, we will derive that Φ is transparent. The derivation, in effect, takes us to $\Phi(S)$ from $\Phi(R)$, for any two true sentences. This will show that mere material equivalence is, despite appearances, sufficient for substitution *salva veritate* within the scope of nonhyperintensional operators such as Φ. Thus, the general result is that if a context isn't hyperintensional, it is transparent.

The derivation runs as follows. We start with (17):

(17) $\Phi(R)$

Given A2 and L1, we can substitute '$\{x\colon x = x \ \& \ R\} = \{x\colon x = x\}$' for the logically equivalent 'R' in (17) while preserving truth. This yields:

(18) $\Phi(\{x\colon x = x \ \& \ R\} = \{x\colon x = x\})$

Given A1 and L3, we don't alter the truth value of (18) by substituting '$\{x\colon x = x \ \& \ S\}$' for the coreferential singular term '$\{x\colon x = x \ \& \ R\}$': these singular terms refer to the same set, i.e., the set of all objects, and we may thus substitute one name for the other. We may thus move from (18) to (19):

(19) $\Phi(\{x\colon x = x \ \& \ S\} = \{x\colon x = x\})$

Now, the final step in deriving $\Phi(S)$ from $\Phi(R)$ is the appeal to logical equivalence once again. Given A2 and L2, we can derive our desired target sentence (20) from (19):

(20) $\Phi(S)$

Being derivable in this way, (20)'s truth value must be the same as the original (17). The upshot is that if assumption 1 and assumption 2 are true with respect to a modifier/connective Φ (i.e., if Φ is not hyperintensional), then (20) may be derived from (17), for **any** true sentences 'R' and 'S.' Hence Φ, insofar as it's not hyperintensional, does allow substitution of material equivalents after all: it is a transparent operator.

It's worth stressing: Such a derivation can be constructed for **any** connective or modifier meeting conditions (i) and (ii): 'necessarily,' 'possibly,' 'before,' and 'because,' but also 'the fact that ——— caused little Billie to cry' and 'the sentence "It will snow in January" stands for the proposition that ———,' and so on. So, the result isn't merely about MCT properties – the third metaphysical view of the three surveyed in the first section – but includes the broader ones that there can be at most one world-bound fact, and that sentences cannot have factlike items as their denotations. Given the importance of these broader results, let us revisit the points in detail.

Aiming the Slingshot at Facts, and Factlike Things

Davidson and others have found the technical result important because they take it to show that sentences cannot stand for 'facts,' or factlike things. Or, more precisely, they cannot when facts are taken to be complexes of ordinary objects, properties, and relations. Indeed, they take it to show that such facts in the plural simply do not exist. The connection between the just-presented technical result and these broader theses is this: if there were multiple world-bound facts, and if sentences stood for them (or something like them, e.g., propositions), then expressions of the form (21) and (22) would have to meet conditions (i)–(iii). But we have just seen an argument that no expression can do this.

(21) The fact that Ottawa is the capital of Canada is different from the fact that ———

(22) 'Ottawa is the capital of Canada' stands for the proposition that ———

Here is the argument specifically against propositions, as I reconstruct it. (It should be straightforward to run the same sort of argument with respect to (21) and facts.) According to the view under consideration, which has facts/propositions containing ordinary objects and such, you don't change from one proposition to another just by changing the name of the thing described. (As noted above, there are other ways of thinking about facts, and factlike things such as propositions, but the view that facts contain

commonplace objects is the most intuitive for reasons already sketched.) Thus, changing the name only matters when the claim is actually about words, as in (1) and (3) above – and claims can't always be about words; facts and propositions are to be autonomous from sentences. These provide good reasons why facts and propositions should be world bound, which in turn entails that the context in (22) must allow substitution of coreferring singular terms. For quite similar reasons, it seems that two sentences which 'say the same thing,' but in different words, shouldn't correspond to distinct facts/propositions; hence logically equivalent sentences should, it may seem, be substitutable in (22) without altering the truth of the whole. In this way we support variants on A1 and A2, here applied to the case (22). But once we have these two premises we can derive, using the argument above, that truth is retained if we substitute any true sentence.

Let's walk through the derivation with an example, namely (23):

(23) 'Ottawa is the capital of Canada' stands for the proposition that Ottawa is the capital of Canada

Suppose (23) is true, as it surely must be if sentences stand for factlike things. Given the logical equivalence of '$\{x: x = x \ \& \ S\} = \{x: x = x\}$' with S itself, for any sentence S, by A2 it follows that:

(24) 'Ottawa is the capital of Canada' stands for the proposition that $\{x: x = x$ & Ottawa is the capital of Canada$\} = \{x: x = x\}$

Given that the singular term '$\{x: x = x \ \& \ S\}$' is coreferential with the singular term '$\{x: x = x \ \& \ R\}$,' as long as R and S are both true, we can apply this generalization to 'Ottawa is the capital of Canada' and 'André Roussimoff died of a heart attack' (both of which are true) to establish that:

(25) '$\{x: x = x$ & Ottawa is the capital of Canada$\}$' is coreferential with the singular term '$\{x: x = x$ & André Roussimoff died of a heart attack$\}$'

Now, we apply substitution of coreferring singular terms to (24). The result of substituting '$\{x: x = x$ & André Roussimoff died of a heart attack$\}$' for '$\{x: x = x$ & Ottawa is the capital of Canada$\}$' is:

(26) 'Ottawa is the capital of Canada' stands for the proposition that $\{x: x = x$ & André Roussimoff died of a heart attack$\} = \{x: x = x\}$

The final step is to note that the complex identity statement about sets is logically equivalent to 'André Roussimoff died of a heart attack.' So, using substitution of logical equivalents a second time, now applied to (26), we can derive (27):

(27) 'Ottawa is the capital of Canada' stands for the proposition that André Roussimoff died of a heart attack

In sum, given that facts and propositions are to be language independent in certain ways, '"Ottawa is the capital of Canada" stands for the proposition that ——' should not be hyperintensional. But we can use the slingshot to show that if the context in (22) is not hyperintensional, then it is transparent. That's disastrous, however, because then this sentence 'stands for' any old true proposition! One can run precisely the same argument, beginning with (21), to show that there is only one world-bound fact.

Responses to the Slingshot Argument

It seems, very much contrary to initial appearances, that modal, causal, and temporal words lack at least one of these properties:

i. Coreferential singular terms may be substituted one for another within the scope of these words without altering the truth of the whole sentence;
ii. Logically equivalent sentences may be substituted one for another within the scope of these words without altering the truth of the whole sentences;
iii. Sentences which are merely materially equivalent – i.e., which just happen to have the same truth value – may not be so substituted.

Also, because of substitution patterns like this, we seem also to be forced to give up world-bound facts and factlike propositions as the denotations of sentences. How is a metaphysician to respond?

One simply cannot give up (iii) as a condition on 'the fact that ——' and such. That's because, put in terms of an example, this would allow 'the fact Ottawa is the capital of Canada' to stand for the fact that Toronto is larger than Halifax! There are, however, at least three ways of saving MCT properties, facts, and factlike things such as propositions, in the face of the slingshot: two ways corresponding to (i) and one way corresponding to (ii). I will take them in reverse order.

First, one can reject the idea that logically equivalent sentences really do stand for a single fact, or factlike proposition. This is explicitly suggested by Barwise and Perry (1981). The proposal is that sentences with different subject matters do not stand for the same fact, even if they are true in precisely the same circumstances. Now (15) and (16), though logically equivalent, clearly have different subject matters, since only the latter talks about sets. So these sentences need not be taken to stand for the same fact. Granted, this makes facts, which are supposed to be built from ordinary elements of the world on the world-bound conception, look a bit more like the

linguistic items that stand for them: facts get individuated in terms of meaning-related criteria such as 'subject matter.' However, this need not jeopardize the distinction between sentences and their meanings. For instance, we can still insist that sentences in different languages can stand for the same fact – as long as they have the same subject matter. And we can even insist that sentences made up of coreferential words, put together in the same way, stand for the same fact. Maybe even transformed sentences can stand for the same fact, if the transformation does not alter the subject matter: e.g., 'Moe kissed Juana' might stand for the same fact as 'Juana was kissed by Moe.' One thus saves world-bound facts, and propositions, by rejecting (ii). (It's less obvious that this move allows MCT properties to have the three features we want; but explaining the ins and outs of that would take us too far afield.)

Second, one can reply to the slingshot argument by denying that (i) really applies. This 'it doesn't apply' move can be pursued in two different ways. Those who follow Frege (1892) maintain that you only have the same fact, or proposition, when not just the referent, but also the sense of the name, is the same. Famously, Frege introduced a two-level semantics, with guises-of-things occupying the level of sense, and the things themselves occupying the level of reference. Crucially for present purposes, being the same fact or proposition is supposed by Frege to require being the same at both levels. So, for example, 'Elton John lives in England' and 'Reg Dwight lives in England' don't really correspond to the same proposition, because the two names differ in sense – even though these two names do refer to the same singer. This is to say that (i) 'doesn't apply' in the sense that it's **false**: coreferring singular terms can give rise to different facts/propositions. It should be clear that making this reply forces one to give up the world-bound conception of facts and factlike things. It is now not objects themselves, but objects described one way or another, that become the components of facts and propositions. This notion of proposition, with different propositions corresponding to the same referents arranged in the same way, is safe from the slingshot. As is the associated notion of fact. For this notion of fact/proposition allows one to reject substitution of coreferential singular terms in the contexts in question – and without that, the slingshot argument cannot get going.

Many contemporary philosophers find this Fregean approach unacceptable, however, for reasons already sketched: it seems like it's the rose itself which smells sweet, not the rose under a guise; and it's the man himself who died of a heart attack; and so on. So it seems, there should be no more to facts than perfectly ordinary objects, properties and relations. Not wanting to abandon the world-bound conception of facts, their alternative response to the slingshot argument is to insist that (i), though it is true, cannot be used as the proponent of the slingshot wishes to, because things like '{x: $x = x$ & André Roussimoff died of a heart attack}' aren't really singular terms. It is in this sense that condition (i) doesn't apply. As Russell (1905) insisted, say these theorists, such expressions are complex definite descriptions whose role is quantificational, not referential: 'the set of objects such that . . .' (which is what this mathematical expression actually means), is not namelike; it is instead more like the quantifiers 'every set of objects such that . . .' and 'some set of objects such that . . ..' And condition (i) above, along with A1, which derives from (i), do not say anything about being able to substitute quantificational expressions *salva veritate*: A1 and (i) only apply to expressions whose function is to pick out an object, without describing it. Put in terms of examples, while it's quite true that 'Elton John is a singer' and 'Reg Dwight is a singer' both stand for the same fact, since these involve two genuine names for the entertainer, it nevertheless is not the case that the description-involving sentences 'The Queen of England lives in London' and 'Canada's head of state lives in London' stand for the same fact. Descriptions do not 'merely pick out the object.' Indeed, say these followers of Russell, what the sentence containing 'the Queen of England' really means is: There exists exactly one queen of England, and every queen of England lives in London. Crucially, therefore, the introduction of things like '{x: $x = x$ & André Roussimoff died of a heart attack}' takes us out of the realm of names (where [i] and A1 apply), and into the realm of descriptions (where they don't). Thus, when one appeals to A1 *et al.* – to move from (18) to (19) in the general case, and from (24) to (26) in the specific case of '"*S*" stands for the proposition that ——' – a fallacy is committed. (Neale, 1995, following Gödel, 1944, gave roughly this reply to the slingshot. Barwise and Perry, 1981 made related points.)

To summarize, then, the slingshot is an argument that deploys very modest machinery to take on several very important metaphysical views. The views include the two broad ones, that there are world-bound facts in the plural, and that what sentences stand for are factlike things, and a related more technical view about what kind of sentence-modifying and sentence-connective operators there can be. The key move in the argument is to start with an arbitrary sentence containing '*R*' and one of the problematic operators ('necessarily,' 'before,' 'because,' 'it's a fact that ——,' etc.), to create a logically equivalent sentence that has

'$\{x: x = x \ \& \ R\} = \{x: x = x\}$' in the scope of the suspect operator. This latter sentence *ipso facto* contains the singular term '$\{x: x = x \ \& \ R\}$,' which, assuming both 'R' and 'S' are true, is coreferential with '$\{x: x = x \ \& \ S\} = \{x: x = x\}$.' Hence, one can deploy the substitution of logical equivalents and the substitution of coreferring singular terms to derive another arbitrary materially equivalent sentence now containing not 'R' but 'S' in the scope of the operator. This shows that if the operator is not hyperintensional, then it's transparent. The three ways to block this argument are (a) to give up substitution *salva veritate* of logical equivalents in the scope of the operator, (b) to follow Frege, and give up substitution *salva veritate* of coreferential singular terms (and with it the world-bound conception of facts) and (c) to insist that substituting expressions of the form '$\{x: x = x \ \& \ R\} = \{x: x = x\}$' is not, in fact, a matter of substituting singular terms, since such expressions are not referential at all, but are instead quantificational expressions.

Pulling back from the details, the slingshot illustrates how careful reflection on a linguistic phenomenon can contribute to debates in metaphysics. In particular, we have taken as our example the role of various principles of substitution *salva veritate* in attacks on facts, propositions, and views about the properties of modal, causal, and temporal properties. The possible replies to the slingshot highlight still further, I think, the importance of linguistic details when discussing metaphysics.

Metapragmatics

C Caffi, Genoa University, Genoa, Italy

© 2006 Elsevier Ltd. All rights reserved.

There are at least three senses in which it is possible to speak of metapragmatics. The first, the most general and potentially generic one, refers to the theoretical debate on pragmatics and its central concerns, its epistemological foundations, and the definition of its relevant object and scope. Metapragmatics in this sense concerns itself with the criteria of pertinence of the discipline, not to state which is the 'best' pragmatics, but to verify the consistency of the basic assumptions, the definitions of the questions to be asked, and the methods to be adopted.

The second, narrower sense, highlights the conditions that make speakers' use of language possible and effective. The task of metapragmatics in this sense is, above all, to make those conditions explicit. This kind of metapragmatics, which can be related to the problem of the universals of human communication, is transcendental in a Kantian sense inasmuch it deals with the constitutive elements of human knowledge.

The third sense is less ambitious than the other two. It is concerned with the investigation of that area of the speakers' competence that reflects judgments of appropriateness on one's own and other people's communicative behavior. In this sense, metapragmatics deals with the 'know-how' regarding the control and planning of, as well as feedback on, the ongoing interaction.

The metapragmatic level is not just *one* of the metalinguistic levels: on the contrary, it is different from them, as the knowledge it refers to concerns not 'the ability to say' but 'the ability to do' (and the ability to say what one does). The metapragmatic level represents the interface between the linguistic and the extra-linguistic: it enables the language user to relate language and world, by checking the

'$\{x: x = x \ \& \ R\} = \{x: x = x\}$' in the scope of the suspect operator. This latter sentence *ipso facto* contains the singular term '$\{x: x = x \ \& \ R\}$,' which, assuming both 'R' and 'S' are true, is coreferential with '$\{x: x = x \ \& \ S\} = \{x: x = x\}$.' Hence, one can deploy the substitution of logical equivalents and the substitution of coreferring singular terms to derive another arbitrary materially equivalent sentence now containing not 'R' but 'S' in the scope of the operator. This shows that if the operator is not hyperintensional, then it's transparent. The three ways to block this argument are (a) to give up substitution *salva veritate* of logical equivalents in the scope of the operator, (b) to follow Frege, and give up substitution *salva veritate* of coreferential singular terms (and with it the world-bound conception of facts) and (c) to insist that substituting expressions of the form '$\{x: x = x \ \& \ R\} = \{x: x = x\}$' is not, in fact, a matter of substituting singular terms, since such expressions are not referential at all, but are instead quantificational expressions.

Metapragmatics

C Caffi, Genoa University, Genoa, Italy

© 2006 Elsevier Ltd. All rights reserved.

There are at least three senses in which it is possible to speak of metapragmatics. The first, the most general and potentially generic one, refers to the theoretical debate on pragmatics and its central concerns, its epistemological foundations, and the definition of its relevant object and scope. Metapragmatics in this sense concerns itself with the criteria of pertinence of the discipline, not to state which is the 'best' pragmatics, but to verify the consistency of the basic assumptions, the definitions of the questions to be asked, and the methods to be adopted.

The second, narrower sense, highlights the conditions that make speakers' use of language possible and effective. The task of metapragmatics in this sense is, above all, to make those conditions explicit. This kind of metapragmatics, which can be related to the problem of the universals of human communication, is transcendental in a Kantian sense inasmuch it deals with the constitutive elements of human knowledge.

The third sense is less ambitious than the other two. It is concerned with the investigation of that area of the speakers' competence that reflects judgments of appropriateness on one's own and other people's communicative behavior. In this sense, metapragmatics deals with the 'know-how' regarding the control and planning of, as well as feedback on, the ongoing interaction.

The metapragmatic level is not just *one* of the metalinguistic levels: on the contrary, it is different from them, as the knowledge it refers to concerns not 'the ability to say' but 'the ability to do' (and the ability to say what one does). The metapragmatic level represents the interface between the linguistic and the extra-linguistic: it enables the language user to relate language and world, by checking the

adequacy of utterances with regard to actual contexts. The knowledge it incorporates leaves traces on the surface of discourse.

The different meanings of the term 'metapragmatics,' with their corresponding different objects of study, have an etymological justification, as they can be linked to the different meanings of the prepositon *metá* in Classical Greek: not only 'above' but also 'beyond.' After all, the term 'metaphysics' is based on a misunderstanding: the volumes by Aristotle entitled *Metaphysics* did not transcend and justify his earlier writings on physics but, simply, because of a chance arrangement, 'came after' the ones on physics. The paradox of metapragmatics, and also its potential oxymoron, is that it 'comes after', though reflecting on, a knowledge that 'comes before' any theory.

Metapragmatics 1: The Need for Metatheoretical Reflections

Pragmatics has definitely come a long way. From being a 'wastebasket,' to use Bar-Hillel's (1971) well-known metaphor, it has become an accredited discipline with an international association, crowded conferences, textbooks, and a monthly journal. Pragmatics is undogmatic, tolerant, and does not demand acts of faith. The reverse side of this tendentially ecumenical hospitality, however, is the heterogeneity of the theoretical proposals it brings together – something that makes it all the more necessary that the theoretical standpoints and the argumentative strategies be clarified. Nevertheless, an agreement both on an (albeit minimal) definition of the field of pertinence and on the assumption of the ideological and theoretical commitments this definition entails is necessary. To achieve this goal, a metatheoretical awareness is needed. So far, these reflections have mainly been practiced on boundary issues (disciplinary and academic), especially with regard to the often disputed borders of pragmatics with semantics and sociolinguistics. Beyond defining goals – something that was appropriate in the first stages of its development – metatheoretical reflections have a right to autonomy. Clearly, any choice regarding the object of study of pragmatics, its domain and, as a consequence, the choice of the most effective descriptive categories and methods, entails a commitment to a metapragmatic view; this commitment and view, however, are most often neither foregrounded nor even made explicit. At times they are simply missing. Nevertheless, such a concern for the epistemological implications of what researchers assume pragmatics is about, is not only legitimate but also necessary, as pragmatic investigation goes beyond the boundaries of linguistics and overlaps with semiotics. Its object is not language, speech, grammar, but human communication (clearly, all these terms ask for metatheoretical definitions). Its subjects are not speakers, but people making (different types of) interactional choices; the study of the latter requires an integrated conceptual framework.

Last but not least, no justification is needed for speaking about meta*pragmatics*; rather, one should ask why one does not commonly speak about metaphonology, metasyntax, metasemantics, and so on.

Wittgenstein (1953) highlighted the constitutional fallacy of any metadiscourse that claims to be foundational, but that is actually just one more linguistic game among many others. Even so, games that consist of asking oneself where the game one is playing comes from, where it leads to, whether its rules have any sense, or if they ought to be changed, are games worth playing. Metapragmatic epistemological reflection is not necessarily transcendental. One way to escape the foundational regression consists in reflecting on how pragmatics speaks about itself, on how it represents itself, on its wording, on its key words, on its predominant metaphors. Much work is needed here. First of all, one has to avoid the risk of new forms of hypostasis (see Borutti, 1984), brought about by certain, apparently harmless, metalinguistic uses. For instance, the use of a definite noun phrase can be idealizing: the risk of an idealization exists whenever one refers to 'the speaker,' who could end up by being an hyperuranian subject, or a lunar *effet-sujet*. Hence, the obvious need for a solid empirical and context-sensitive 'anchorage.'

As noted, pragmatics is tolerant; some would even call it loose. Yet, if one looks at the literature labeled pragmatic, one is struck by the frequency of such words as 'rules,' 'maxims,' 'principles.' From the available data, one tries to infer rules and principles. One could even imagine a (superego-like) need for normalization; a need that is clearly understandable if one considers the messy nature of the object and the need to define analytical instruments with which to infer generalizable results. On the one hand, it is a fact that pragmatic mistakes are much more compromising than grammatical ones: there is nothing worse for an interactant than the *pragmatica sanctio* whereby his/her syntactically and semantically well-structured utterance is inappropriate, ineffective, unhappy, inadequate to his/her wishes and aims. On the other hand, 'normativeness' assumes that what is regulated, i.e., the basic units to which rules and regulations apply, is not controversial. But, once again, this is a matter of metatheoretical choice (see Mey, 2001: 176ff.; Verschueren, 2003).

Metapragmatics 2: On the Possibility Conditions of Action and Interaction

Communication

The second type of research that can be labeled 'metapragmatic' studies the possibility and felicity conditions of communication. Whereas in other research areas, such as text linguistics, there have been attempts to define the constitutive rules – what makes a text a text, the *quidditas*, rather than the *qualitas* of the text, identified in coherence – in pragmatics attention has mostly been given to regulative rules or principles: how to cooperate, be kind, polite, etc. In this regulative sense, traditional rhetoric, as it lists and correlates locutionary and perlocutionary strategies, is a distinguished and sophisticated precedent (*see* **Rhetoric, Classical**). One limit of rhetoric is that it ignores the action level of language, defined by Austin as the illocutionary level of a speech act, which can be taken to represent the basic unit of analysis both in conversation analysis and in pragmatic linguistics.

Normativeness, as noted, presupposes that what is normalized is clear. Nevertheless, the following questions remain open. What is constitutive of an action? What is constitutive of an interaction? What must necessarily, not optionally, hold for an action of a certain kind to be performed? What units of action are constitutive of a given interaction?

In this type of metapragmatics, for instance in research on dialogue-constitutive universals, to use Habermas's (1971) label, the metaphysical risk is particularly tangible. The same risk is encountered in the presumed identification of universal speech acts, particularly if they are transferred onto syntactic units and inflectional moods (the illocutionary acts of statements, questions, and commands as unproblematically reflecting the indicative, interrogative and imperative moods (*see* **Speech Acts and Grammar**)). The problem of identifying basic acts – whether universal or not, and whether or not associated with specific syntactic forms – is related to the problem of the conventions underlying the performance of an act. In its turn, this problem is linked with the problem of consensus: what is the consensus that allows us to define the interactional sequence *X* as *Y*? Is there a pragmatic common core allowing a cross-cultural comparison of communicative behaviors and, if so, what does it consist of?

Here, a wide and by no means uncontroversial area of research opens up. Shared metapragmatic knowledge concerns knowledge of culture-bound and group-bound action frames. Members of a given community, in a given phase of its history, are able to produce and recognize types of linguistic action, and assign, prospectively or retrospectively, an utterance 'token' to a 'type' of action, by describing *X* as *Y*. Behind this possibility of performance and recognition of linguistic action one can imagine, in a Kantian fashion, several conditions:

a. *Conditions of 'thinkability,'* i.e., conditions underlying the possibility of thinking types of actions. These conditions are registered in the lexicon, for instance, as speech act names or illocutionary force indicating devices; they deal with the 'what is,' the essence. The most famous attempt to define constitutive rules of speech acts was made by Searle (1969) (*see* **Speech Acts**). Such attempts can be related to research in Artificial Intelligence (AI) and cognitive psychology, in particular on action frames and on how global patterns are inscribed in the speakers' memory. The major difficulty met by this kind of investigation derives from the fact that there is not just one way to perform an action; neither is there a one-to-one relationship between linguistic form and action type: in short, there is no correspondence between sentence types and utterance types.

b. *Conditions of feasibility*, i.e., conditions regarding the system of aims and expectations within which the action is performed; they deal with the 'how to do,' the procedure. This kind of knowledge concerns the existence and functioning of intersubjectively recognizable strategies by which people match different kinds of action to different actual contexts. The Gricean maxims form an example of proposals made in this area, which can be related to praxeology, inasmuch as they deal with effective acting. However, further research – including cross-cultural work on politeness – has underlined that Grice's maxims are strongly ethnocentric; so, they must be reconsidered, maybe even discarded as possible candidates for the role of pragmatic universals (*see* **Maxims and Flouting**).

c. *Conditions of recognizability.* These conditions deal with questions such as 'where did you get this from,' 'what made you say this,' and so on, hence with interpretability. This question is related to the study of the different kinds of linguistic and paralinguistic means and markers (lexical, but also morphosyntactic, textual, prosodic, kinesic) available in different languages. Their conventional nature is not given once and for all, but changes over time and space. They narrow down the range of possible reasonable interpretations, on the part of the interpreters, of their partners' communicative behaviors, in abductive processes, by trial and error, through which the assignment of signification is negotiated. Obviously, the more shared knowledge the interactants have, and know they have, the more often they will leave out

the intermediate steps in their dialogues, which, as a result, will be mutually understandable by them, but not by an external observer.

From a logical point of view, the three types of conditions are arranged in a hierarchically descending sequence, while from a methodological point of view this sequence is reversed. From a 'practical' point of view, i.e., from the point of view of what is really happening in human interaction, these conditions come together, because the social actors rely and act on the three kinds of conditions simultaneously. The main problem is that of relating these three types of conditions to the conventional intersubjective practices of everyday interaction where cognitive structures and sociopsychological constraints interact. The difficulties brought about by Searle's constitutive rules, and the rules' inadequacy as micro-models of linguistic action and communicative behavior have been highlighted by Kreckel (1981) (*see* **Principles and Rules**).

Empirical-Conceptual Approach

The term 'metapragmatics' has been applied in comparative lexical research, particularly as it has centered on verbs defining linguistic actions, i.e., on speech act verbs (*see* **Speech Acts: Definition and Classification**). Such an approach, defined as 'empirical-conceptual,' starts from the assumption that an investigation of the lexical structure, of the semantics of verbs used to describe speech acts, throws light onto the nature of linguistic action (Verschueren, 1985). Such research has the advantage of bringing the often abstract reflections of classical speech act theory closer to the ways in which linguistic actions are described in individual languages. Now, given that the lexicon forms an interface between pragmatics and grammar, and that the study of the lexicon thus represents an important empirical 'anchorage,' it is still also true that mere lexical research is inherently inadequate for the analysis of interactive dynamics. It is indeed necessary, if actual interaction is not to become irrelevant, to correlate the investigation of the typologies of the verbs that people use to describe linguistic actions with the investigation of what people seem to know 'in real time,' 'live,' about the use of their own language in context. The study of the types of linguistic items (among them lexical items) must be linked to the study of the types of their underlying contextual features and criteria of appropriateness.

It also is important to clarify the level of abstraction at which one is working, so that pragmatic metalanguage is not at the same time both the *definiens* and the *definiendum*: the interiorized conceptualization of the linguist as a native speaker of a particular language should not predetermine his/her selection of the relevant features of a speech act in relation to a (presumably universal) common core.

This type of metapragmatic research has the merit of positing a methodological connection between speech act taxonomy and folk taxonomies. It is well known that languages, those powerful instruments of conceptualization, segment the external world and natural phenomena in different ways, from the color spectrum onward – a much-quoted example both in favor of, and against, the so-called Sapir-Whorf hypothesis. Unlike colors, though, linguistic actions do not exist *in natura*; they do not come before language use, nor are they separable from it. Regardless of the power of the means we are able to mobilize, a privileged extraterritorial theoretical standpoint from which to look at linguistic actions does not exist.

Metapragmatics 3: The Management of Discourse

Common Knowledge and Reflexivity

The two distinctive features here are the reference to common knowledge – both shared knowledge and folk theories – and reflexivity. Significantly, they coincide with the most resistant barriers that separate artificial intelligence from the human intellect: common sense (a notion which is epistemological, not ideological, as pointed out by Parret, 1983) and reflexivity, i.e., the human intellect's capability and transcendental possibility of thinking (and speaking) about its own thinking (*see* **Reflexivity**).

Reflexivity is also one of the most distinctive features of natural languages, marking them off from other semiotic systems precisely by this capacity of describing themselves. The complex issue of reflexivity, seen as merging with indexicality and encompassing all metapragmatic activities, has been investigated from an anthropological, cross-cultural viewpoint by Lucy (ed.) (1993). From a more restricted, linguistic viewpoint, an aspect of reflexivity can be found in the possibility that speakers have of communicating on the communication they are engaged in, by defining it and by confirming or modifying the definitions given by themselves and by their partners. Such 'editing,' along with self- or other-initiated repairs, is rooted in metapragmatic reflexivity; so are reformulations, evaluations, metadiscursive comments, and requests for explanations through which mutual understanding is negotiated. In texts and discourse, there are classes of markers – e.g., Gumperz's (1982) 'contextualization cues' – and metacommunicative

utterances whose role it is to ensure dialogue management in terms of communicative effectiveness.

When tackling a speech sequence, not only can one describe it, give it a name, but one also can judge whether it is appropriate to the situation. One can understand whether one has chosen – among adequate communicative options – the one that best fits the context; if this is not the case, one can retrace one's steps and correct oneself. One can, in an overall communicative strategy, negotiate the degree of directness, explicitness, or politeness as one goes along. One can decide whether one has said the right thing at the right time in the right way, or whether one has made a tactless remark. If the utterance was too elliptical or cryptic, ironical, or digressive in relation to a conversational topic (hence requiring adventurous inferential steps), one can ask for explanations and redefine the context and its presuppositions, thereby reshuffling the assignment of rights and duties among the partners.

All such skills are not predicated on clumsy beginners (the 'model readers,' in the sense of Eco (1979), of many textbooks and grammars) but on social actors and 'competent readers' (see Mey, 2000) who use their communicative know-how, not with awe but with pleasure. At the other end of the scale of metapragmatic awareness are gaffes and jokes. This shared metapragmatic awareness is not only linguistic but also semiotic, encyclopedic, and constitutionally intertextual. It refers to a knowledge that concerns not only language as social (culturally and historically determined) behavior but also our 'being in the world.' The problem of metapragmatic appropriateness, being close to the problem of style, lies in that dialectic relationship between expectation and surprise that is peculiar to the communicative exchange. Regarding to a given system of expectations, there will be more or less marked choices. A choice is all the more significant when it is less foreseeable (see Arndt and Janney, 1987): the more it eludes ceremony and routine, the more it communicates. In this sense, the literary text is highly informative in its non-redundancy (see Lotman, 1977). Once one is engaged in a routine, and has chosen a communicative register, the most remarkable and revealing choice will be the unexpected one, the sudden change in the linguistic, intonational, and proxemic register.

Monitoring

A considerable part of metapragmatics as discourse management can be ascribed to monitoring, to definitions of the situation furnished by the interactants as they go along. Ethnomethodologists call these definitions 'glosses,' specifying that these are not an exception but the rule in spontaneous verbal interaction. Interaction management includes a control on discourse which refers to the conditions of feasibility and interpretability mentioned in 'Metapragmatics 2' above. This monitoring can be found at a macro-level, e.g., in the allocation of conversational rights, in the kind of sequence and the thematic development of turns, or at a micro-level, in the explicit focusing of speech on speech and on its micro-organization (e.g., utterances like 'What I mean is . . . ,' or, in written texts, the heading of a paragraph). Every utterance that not only performs some kind of action but also describes it, venturing a description of 'what is happening' (which it is up to the hearer to validate), plays a monitoring role. Pragmatics started as the analysis of ritual performative utterances which do what they say and say what they do. A metapragmatic paradox is that, in everyday speech, if I want to do something, I must not say I am going to do it. In order to 'state,' for instance, I must not say 'I state that.' If I do, it means I am doing something else. In order to perform an action, I must avoid naming it. In discourse, however, there can be a syntactic and temporal displacement between an action and its description. This is what happens in the metacommunicative acts that describe a speech sequence from an illocutionary point of view (e.g., 'This was a promise, an order, a simple statement,' etc.). Because this kind of description is an important means of orienting the interaction processing, the metacommunicative acts can be referred to as 'speech control': they offer a labeling of preceding actions (anaphorically) or subsequent ones (cataphorically), and they focus on the simultaneous presence in discourse of linearity (a preceding sequence *X* can be classified as *Y*) and a depth (the speaker is both the involved participant and the observer of him/herself and of the interaction). Discourse has both a sequential and a hierarchical organization **Discourse, Foucauldian Approach**. Finally, it is worth noting that metaillocutionary qualification is often also metatextual and cohesive (e.g., 'That was a question'), but not *vice versa*.

From a (not only) terminological point of view, 'metapragmatic' is a hyperonym in relation both to 'metatextual' (comprising those mechanisms which enable one to signpost one's way through the text, e.g., textual deixis) and to 'metaillocutionary' (comprising those mechanisms that make explicit the kind of illocutionary act, e.g., as metacommunicative acts). Finally, if 'metacommunication' is meant as something more limited and more precise than as defined by Watzlawick *et al.* (1967), for instance, if one takes it as qualifying a global communicative modality (e.g., 'I was only joking'), then it falls within the range of metapragmatics.

Applying Metapragmatics

Conflicts have their origins in different definitions of the same situation. As Watzlawick *et al*. state, "The ability to metacommunicate appropriately is not only the *conditio sine qua non* of successful communication, but is intimately linked with the enormous problem of the awareness of self and others" (1967: 53).

Like philosophy and anthropology, metapragmatics has 'therapeutic' potential. At any level, both theoretical and everyday, whenever a social group or a speaker look critically at themselves, maybe making corrections, adjustments or clarifying comments on their discourse, the dangerous identification between Self and *the* point of view is broken, and the road opens up to the legitimization of other points of view. The 'meta-' determines that space in which the other's perspective can be accepted. Moreover, metapragmatic awareness enables the speaker not to adhere to the established sociocommunicative roles and routines so closely as to be totally absorbed by them. Metapragmatics specializes in the control of the argumentative conditions and strategies, lending itself easily to becoming a critical instrument of fundamental importance in digging up and highlighting the underlying presuppositions as well as the different kinds of the unsaid. It is clearly helpful in, for example, first language acquisition (see, among others, Gombert, 1993; Bernicot and Laval, 1996) and second language learning, in the cross-cultural comparison of the ways in which a linguistic and social group represents and recognizes itself (see, among others, Blum-Kulka, 1992), in the analysis and discussion of any, more or less openly authoritarian and unidirectional, discourse (see, among others, Jacquemet, 1992). Metapragmatic competence is potentially subversive, such as when it enables the hearer to verify that the preparatory conditions of appropriateness of a speech act are fulfilled (as an example, imagine a patient saying 'Why are you doing this?' to his/her doctor).

Metapragmatic knowledge is a crucial step toward an ecology of communication.

Conclusions

The possible meanings of metapragmatics mentioned at the outset are not mutually exclusive; on the contrary, they can be related to, and even be integrated with, each other. For example, if one chooses to stress metapragmatics in sense 3 (see 'Metapragmatics 3') rather than in senses 1 or 2, this is a theoretical choice (see 'Metapragmatics 1'). One can even claim that the only non-transcendental way of legitimizing metapragmatics (relevant for sense 1) is one that records and analyzes specific communicative practices in socially and historically determined contexts. Its not being indifferent to individual languages is a major requirement for a non-metaphysical metapragmatics. Another requirement is that of not being indifferent to the ways in which people express their knowledge, e.g., by feedback on and adjustments to, what they are doing communicatively, thus building up the interpretation which is the result of the cross-inferential work on the part of all the participants involved. A systematic account of this knowledge is a difficult interdisciplinary enterprise, which cannot be merely introspective. While pragmatics has experienced, there is the risk of replacing a metaphysics of introspection with a metaphysics of empirical data, in an excessive fragmentation of the research work and its findings that leaves no room for any significant generalization.

One possible theoretical choice and one that in the present, extremely varied and lively state of the debate, can only be a partial choice, consists in denying the existence of any clear-cut division between 'scientific' metapragmatic knowledge and the metapragmatic knowledge of the users of a language, and instead, assuming there exists a *continuum*, at a smaller or greater distance from the object, viz.: the use of the language.

The basic assumption which is relevant to the first sense of metapragmatics as metatheoretical reflection, could then be to hold that in pragmatics, there are different degrees of explicitness in, but no differences in nature between, folk and scientific theories. The metapragmatic paradox is that the traditional metatheoretical top-down control is valid only if it is kept down to earth.

High-sounding transcendencies are replaced by inevitably partial analyses of what is constitutive of the communicative practices in which one is involved, of the ways in which awareness of self and of others comes out, not just in order to speak about the world, but to change it, and oneself, through discourse. The program of metapragmatics (its Manifesto) might be the (meta-)pragmatic sentence that Socrates (had he not been forced by the tyrants to drink the hemlock) would have added to his motto 'I know I don't know': 'I don't know enough that I do know.'

Metasemiotics

The empirical study of metasemiotics derives from the general semiotic framework proposed by Charles Sanders Peirce, who endeavored to explore the foundations of knowledge in a manner not unrelated to Kant's exploration in *The Critique of Pure Reason*. But Peirce viewed our ability, as humans, to make contact with an external reality as the result of complex layered sign processes. He developed a hierarchy of signs, based upon a series of trichotomies – the most often-quoted of which has been that of the icon, index, symbol. Within each trichotomy, one component is closest to experience, another closest to knowledge, with the third term standing between them. Thus, icons are closest to experience and symbols to knowledge.

Metasemiosis and Metapragmatics

G Urban, University of Pennsylvania, Philadelphia, PA, USA

Metasemiotics

The empirical study of metasemiotics derives from the general semiotic framework proposed by Charles Sanders Peirce, who endeavored to explore the foundations of knowledge in a manner not unrelated to Kant's exploration in *The Critique of Pure Reason*. But Peirce viewed our ability, as humans, to make contact with an external reality as the result of complex layered sign processes. He developed a hierarchy of signs, based upon a series of trichotomies – the most often-quoted of which has been that of the icon, index, symbol. Within each trichotomy, one component is closest to experience, another closest to knowledge, with the third term standing between them. Thus, icons are closest to experience and symbols to knowledge.

The relevance of the Peircean hierarchy to metasemiotics is that signs closer to the side of knowledge depend on those closer to the side of experience in a chain-like fashion. Thus, a symbol, where the relationship between a sign vehicle and its meaning is based on a learned rule (as in the relationship between a word and its meaning in language), is closest to the side of knowledge. However, it cannot be understood as having anything to do with experience unless it is related to indices – where the sign vehicle is connected to its object or meaning by spatio-temporal contiguity. An index is closer to the side of experience than a symbol – since the index involves the perception of contiguities in space and time – but it in turn depends upon icons, where the icon involves recognition of similarities rather than contiguities. Hence, symbols depend on indices, which in turn depend on icons.

Can one say that these relationships of 'depending on' that connect symbols to indices to icons in a chain of semiosis are forms of 'aboutness' or representation analogous to the relationship between a metalanguage and object language? The parallel is not exact, since the metalanguage–object language connection involves fully explicit or conscious focus on the object signs, and this cannot be said of the semiotic chain just mentioned. However, the Peircean chain of semiosis does involve something resembling metasign–sign relationships. Consciousness of the object sign is at one end of the chain, with the earlier layers progressively less accessible to consciousness, albeit presumably closer to experience. While consciousness and knowledge are not, from this perspective, identical – knowledge can be implicit or operational – consciousness is associated with the form of knowledge that is maximally distant from experience. In any case, metasemiotic research, in recent decades, has included metasign–sign relationships that are not of the explicitly representational sort.

The Peircean semiotic framework, as utilized to analyze speech and linguistic communication more generally, was taken up most explicitly by Roman Jakobson (1960). In his formulation of the six types of sign function operative in language, Jakobson includes the metalinguistic function, where the focus of the message is on the code, that is, on the very representational relationship of the object-language signs to their referents. This most closely parallels the accepted metalanguage–object language distinction, and is clearly metasemiotic. However, of the other functions, the poetic function – where the focus of the message is on the message itself – is also metasemiotic in the present sense, even though the connection between the metasign (the poetic form of the message) and the sign (the message) is not a matter of explicit reference. Jakobson points out the converse functional relationships of the two types of metasemiosis.

Some of the other functions of language should perhaps be regarded as implicitly metasemiotic as well, for example, the expressive and conative functions, where the focus of the message is the speaker, in the former case, and the addressee, in the latter. To be regarded as metasemiotic, the focus on the speaker would have to be on the individual person as speaker, that is, as engaged in a speech act, rather than, say, as a person in general. Similarly, in the case of the conative function, the focus of the message would be on the addressee as addressee, that is, as intended recipient of the message.

Because of the difficulty of analyzing metasign–sign relationships that are not based on explicit reference, one direction that metasemiotic studies have taken is towards referential aspects of language that are about speech. The ethnography of speaking, associated with the founding work of Dell Hymes (1974), took as one of its central objects of investigation the ethnographically describable components of languages that refer to the act of speaking itself. In English, for example, one can study the deployment of verbs of speaking: *to say*, *to question*, *to pronounce*, *to repeat*, and so forth.

But other empirical researchers have felt limited by confining investigation just to explicit portions of a linguistic code that refer to speaking. Erving Goffman developed what would become a major line of research on framing. The frame tells one how to interpret what is going on in a specific communicative situation. Thus, we distinguish the interpretation of speech as used within a theatrical play from seemingly identical speech used in an everyday context, an observation also made by Gregory Bateson (1972), who refers to the flow of signs of such framing as (generally unconscious) metacommunication. (Bateson was interested in the implications of this for psychiatric work, among other areas.) Frames, like theatrical plays, also permit rekeyings. For example, the rehearsal of a play can be understood as distinct from the play itself, and also distinct from a rehearsal that occurs within the performance of a play. From the point of view of general metasemiotics, it is important that the metasigns that instruct us as to how to interpret the signs (the play, for example) need not be themselves explicitly referential, in the way in which metalanguage is.

Arguably the most important development in the latter part of the 20th century in the area of metasemiotics was Michael Silverstein's distinction between metasemantic and what he called Metapragmatic usages (see especially his 'Metapragmatic discourse and metapragmatic function') (Silverstein,

1993). Metasemantics covers the realm usually studied in the metalanguage-object language literature, and seems to be what Jakobson had in mind in formulating his notion of the metalinguistic function. The distinction between metasemantics and metapragmatics parallels that between the linguist's narrow reading of semantics and pragmatics. Where 'semantics' refers to the explicit meanings of words, deriving, as per Ferdinand de Saussure, from their systematic relations to other words as part of grammatically formed language – the realm of what Peirce called symbols – pragmatics refers to the meanings conveyed by speech that must be inferred from context and paralinguistic features, including intonation contours and voice qualities. The corresponding Peircean sign modes for pragmatics are the icon and the index. In an often repeated example, suppose someone says: "My, but it's chilly in here!" when there is a window open with cold air blowing through it next to where the addressee is seated. The semantic statement may take on the pragmatic meaning of a request to close the window. Correspondingly, if there are semantic codes for interpreting the explicit meaning of words, there are also pragmatic codes for making inferences about implicit meanings.

'Metapragmatic' refers to linguistic signs that are about the pragmatic code, about how to interpret the extrasemantic meanings encoded in speech. Much of the ethnography of speaking research falls into the realm of metapragmatic investigation, for example, in studying the words, in a given language, that describe different ways of speaking. In English, the word 'to cajole' makes explicit reference to a speech act wherein the speaker is endeavoring to persuade the addressee by pragmatic means such as distractive flattering or suggesting possible benefits, without explicitly promising them. The word is thus explicitly metapragmatic in denotation.

But the distinction between metapragmatics and metasemantics does much more. By opening metasemiotics to the analysis of sign–object relations that are not symbolic (or semantic), it also opens the possibility that metasign–sign relations may be nonsymbolic (i.e., pragmatic, based on indices and icons). This brings into explicit focus the idea of frame analysis, in Goffman's sense (1974), and metacommunication, in Bateson's. We can think here of a two-by-two matrix, where the semantic-pragmatic distinction applies to either the sign–object relationship or the metasign–sign relationship, as in Figure 1.

While the ethnography of speaking has included more than is indicated here, we may perhaps use the phrase 'ethnoscience of speaking' as a convenient shorthand for studies of ethnographically describable explicit linguistic formulations of the pragmatic uses of language.

Figure 1 The semantic/pragmatic distinction can apply to either the sign–object relation or the metasign–sign relation, generating different areas for empirical investigation.

The recent language ideology research (see, for example, Schieffelin *et al.*, 1998) is part of metasemiotics, but much of it falls into the quadrant of pragmatic metasign–sign relations coupled with semantic sign–object relations. This is true, for example, of Jane Hill's work on Mock Spanish. Hill (2001) marshals numerous examples to show that Spanish phrases are deployed in American English in ways that devalue Spanish as a linguistic code. The phrase "hasta la vista, baby" – used in Hollywood films – is one in which the speaker devalues the addressee, in this case, lets them know that they are about to be killed. The idea that Spanish as a code is devalued for American speakers is nowhere explicitly formulated. That is, the metasign–sign relationship proposed by Hill is itself pragmatic and inferred. But the metasign is about the Spanish language as code, that is, about semantic sign–object relations.

Recent research on ritual laments, taking those laments as metasigns, falls into the final quadrant, in which both metasign–sign and sign–object relations are pragmatically interpreted. The lament is a metasign whose object is crying, including the specific instance of crying contained in the form of the metasign. Because the metasign is an icon of the sign, it is pragmatically related to that sign, and must be inferred rather than being explicitly formulated. Furthermore, it is not about the sign (the crying) as semantic, but rather about the sign as pragmatic, as an expressive index and social act. One salient meaning of the metasign appears to be that the instance of crying should be interpreted as a desire for social contact, a way of reaching out to other people, and of showing one's conformity to the social norms that govern relations between those people. All of this is accomplished without the aid of semantically explicit metasigns (Figure 1).

An important work on language, which includes Silverstein's paper mentioned above, is the volume

edited by John Lucy (1993) and entitled *Reflexive language*. One of the key theoretical questions raised in this volume and other recent work is the relationship between metasemiotics and consciousness or awareness. This research seems to suggest that consciousness of signs is maximal where the metasigns interpreting them are semantic. Correspondingly, pragmatic metasigns permit the manipulation of signs – as in the case of mock Spanish, for example, or advertising – relatively outside the awareness of the recipients of the signs.

Although awareness of signs may be maximal where the metasigns interpreting them are semantic, this does not mean that the metasigns are necessarily transparent to the object signs – unproblematic encodings of truth. There may be simultaneous pragmatic effects skewing the semantically encoded awareness. In his metasemiotic examination of philosophical discourse in the book *Talking heads: language, metalanguage, and the semiotics of subjectivity*, for instance, Benjamin Lee (1997) argues that Descartes' cogito argument – "I think therefore I am" – was influenced by implicit linguistic analogies between the verb *to think* and verbs of speaking: *I think* . . . is like *I state* . . . ; *I aver* . . . ; *I question* . . . ; and so forth. Such pragmatic skewing of semantic metasign–sign relations is the foundation of much recent renewed interest in the Sapir-Whorf hypothesis.

Metasemiosis is not only a neutral reflection upon culture (whether accurate or skewed). It is also an active force, thanks to its ability to evaluate and affect, as well as represent. A key area in which metasemiosis plays an active role is in the circulation of signs (notably of discourse) in the world – a theme taken up in the book by Greg Urban (2001) entitled *Metaculture: how culture moves through the world*.

Metasemiotic research is on the threshold of producing new insights into questions of agency and intentionality in social action, as well as a clearer understanding of the nature of consciousness and knowledge. Humans in interaction are more and more seen as unlike billiard balls bumping up against one another, and therefore meaning (semiosis) is seen to play the causal role in human conduct. So metasemiotics is the tool of choice for revealing the pathways and processes through which agentive causation takes place. Correspondingly, if consciousness is the product of a complex pathway of metasign-to-sign interconnections, leading from experience to knowledge, then metasemiotic investigation will prove essential for the clarification of fundamental problems about cultural relativity and truth.

Metathesis

J Stonham, University of Newcastle upon Tyne, Newcastle upon Tyne, UK

© 2006 Elsevier Ltd. All rights reserved.

Metathesis involves the transposition of elements in a string, resulting in a reordering of the segments. As an example, the English form *ask* may be found to alternate with the form *aks,* indicating a transposition of *k* and *s*. The vast majority of cases arise in order to satisfy some well-formedness constraint involving the necessity of breaking up clusters, the need to adhere to some segmental ordering hierarchy, or the repair of phonotactic violations, as suggested by Grammont (1933: 339):

> La métathèse consiste matériellement en ce qu'un phonème quitte sa place originaire pour aller en prendre une autre à une certaine distance de la première. La cause principale de ce phénomène est le besoin de donner aux syllabes ou aux mots une constitution phonique plus commode. ["Metathesis mainly consists of a phoneme that moves from its original site to take up another place at a distance from the first. The main reason for this phenomenon is the need to give syllables or words a more convenient phonic constitution."]

Hock (1985) remarks that metathesis is frequently irregular and sporadic, but then goes on to investigate the possibility of regular metathesis, citing the case of Modern Persian discussed below. The focus here will be on the case of regular, rule-governed metathesis.

A Typology of Metathesis

Ultan (1971) is one of the earliest attempts at a systematic typological study of metathesis. He observes that the most common context for the appearance of metathesis is the combining of morphemes that results in phonologically undesirable results, necessitating some form of restructuring to repair the violation. He categorizes instances of metathesis by means of a set of distinctive features: linguistically motivated, involuntary, and systematic, providing a typology of types of metathesis. While Ultan discusses a wide range of phenomena, including subject-aux inversion, under the rubric of metathesis, most linguists would limit the range of metathesis to the reversal of two segmental units.

Some types of metathesis may involve psycholinguistic phenomena such as processing problems that result in forms commonly labeled spoonerisms or slips of the tongue, for instance, *cuff of copy* instead of *cup of coffee* (Fromkin, 1971) (*see*), as well as various types of speech pathology (*see*). Systematic, paralinguistic forms, outside the realm of linguistic metathesis, include conscious manipulations of forms to alter existing words or phrases, either in play or as a form of euphemism or disguise. An example of this is the Sinhala disguised speech form *hike pulak* for the original *puke hiluk* 'asshole' (*see* **Slang, Argot and Ingroup Codes**).

Among the linguistically motivated, systematic cases, we may distinguish two varieties, synchronic and diachronic. The former is the focus here, while the latter is discussed in greater detail elsewhere (*see* **Diachronic Aspects of Metathesis**).

Phonologically Conditioned Metathesis

Of the numerous instances of synchronic metathesis cited in the literature, the vast majority must be considered to be of the phonologically conditioned type. Since most cases of metathesis arise through the juxtaposition of morphological units, phonological conditioning must be interpreted as being based solely on the ordering of segments, without regard to the morphemes concerned. Grammatical conditioning, on the other hand, refers to the use of metathesis to mark some grammatical category, i.e., metathesis as a morpheme.

In West Saxon, a sequence of /k/ followed by /s/ in the same syllable was disallowed, and therefore, the two elements were transposed, giving the permissible sequence /sk/, as in *disc* [disk] (sing) 'dish' but *dixas* [diksas] (PL) or *fisc* (sing) 'fish' but *fixas* (PL). The deletion of a final vowel in PERSIAN may result in a violation of the sonority hierarchy that is repaired by metathesizing the underlying obstruent-sonorant sequence to produce the acceptable forms *surx* (< suxra) 'red' and ars (< asru) 'tear$_N$.' Similarly, in Yagua, a Peruvian language, the juxtaposition of the first person singular possessive prefix, *ray-*, to a base results in the reversal of segments, for example, *ray + paa* 'bread' *rapyaa* 'my bread' or *ray + tooya* 'fish-hook' *ratyooya* 'my fish-hook.'

HEBREW disallows the sequence of stop + strident coronal fricative across a morpheme boundary, so when the prefix *hit-* is attached to a base containing an initial coronal fricative, the /t/ of the prefix is transposed with the fricative, as in Table 1.

Table 1 Hebrew hitpa'el binyan

hit + paʔel	>	hitpaʔel	'dressed himself'
hit + xapes	>	hitxapes	'was sought'
hit + saper	>	histaper	'got a haircut'
hit + ʃalem	>	hiʃtalem	'was completed'

Table 2 Rotuman aspect

Complete	*Incomplete*	
ŋoha	ŋwah	'peep'
leka	lyak	'go'
hosa	hwas	'flower'
tiko	tyok	'flesh'

Table 3 Clallam aspect

Nonactual	*Actual*	
čk^{ω}u	čuk^{w}	'shoot'
xči	xič	'scratch'
q̇qi	q̇iq	'restrain'
ċsə	ċəs	'hit'

Table 4 Sierra Miwok stems

Primary stem		*Fourth stem*	
kalaŋ	'to dance'	kalŋa	'a dance'
ʔumuč	'to approach winter'	ʔumču	'winter'
tuyaŋ	'to jump'	tuyŋa	'a jump'
ʔawin	'to play'	ʔawni	'a game'

Table 5 Motivations for the use of metathesis

Motivation	*Languages*
a. Sonority Hierarchy restrictions	Persian, Yagua
b. Phonotactic constraints	West Saxon, Hebrew
c. Prosodic shape requirements	Straits Salish, Rotuman
d. Templatic requirements	Sierra Miwok

In all of the above cases, we may consider the use of metathesis to be a phonological repair strategy, ensuring that the items conform to a preferred shape.

Grammatically Conditioned Metathesis

Cases have been attested that employ metathesis as a grammatical device, in effect acting as a morpheme by itself rather than as the consequence of the juxtaposition of two morphemes that results in a phonological environment requiring metathesis to repair the structure.

One of the earliest discussions of grammatically conditioned metathesis is an article by Thompson and Thompson (1969) entitled 'Metathesis as a grammatical device,' which presents several cases of what appears to be a metathesis morpheme. For example, the distinction between the 'complete' and the 'incomplete' phase in the Austronesian language, Rotuman, is realized by a metathesis of the final consonant and vowel of the forms in Table 2.

One thing to notice about the incomplete phase is that it always involves the reduction of the form by one syllable, with the concomitant change of the first vowel to a glide.

Another case discussed in Thompson and Thompson (1969) is that of Clallam, a member of the Straits Salish group (Salishan languages). There are several ways to form the actual aspect (similar to the imperfective) in Clallam, involving the use of -insertion, reduplication, and the permutation of consonant and vowel, i.e., metathesis, as in Table 3.

In all cases the syllable structure changes from CCV to CVC. In Sierra Miwok, a member of the Costanoan family (Penutian languages), verbal roots appear in one of several different forms: a primary, second, third, and fourth stem for most verbs. Freeland (1951: 96) states that "[t]his variation in the rhythmic pattern of the verb stem must, I think, be regarded as in some measure having grammatical value in itself . . . ." According to Freeland, the metathesis is always of the same type, involving the reversal of order of consonant and vowel in the second syllable of a stem, as in Table 4.

All cases of metathesis in Sierra Miwok are the result of the imposition of a CVCCV template (*see* **Template Morphology**) to which phonemes are linked, much as in the binyanim of the Semitic languages.

Motivation

A further question concerns the motivation for the use of metathesis. Previous discussion suggests several reasons for employing metathesis, all involving the need to restructure a form in some fashion, as shown in Table 5.

Thus the rearrangement of elements or the concatenation of morphemes may result in the juxtaposition of elements that are not optimal. Metathesis is one strategy for optimizing the results.

Theoretical Models of Metathesis

The subject of metathesis is a potentially troublesome one for linguists because of the kind of theoretical machinery required in order to provide an adequate analysis of the phenomenon. Most other linguistic phenomena are amenable to more or less linear analyses, perhaps involving the separation of tiers to explain certain phenomena, but no matter how one reconfigures separate tiers, there would appear to be no solution to the problem of metathesis.

Note that metathesis defies the use of strictly concatenative approaches; it violates notions of sequentiality and linearity in language, demands

context-dependent structure-changing, and requires overly powerful theoretical machinery. It has been invoked as a key example of the need for process-based morphology in such works as Anderson (1992), Janda (1984), and Zwicky (1988). The usual argument is that combinatorial models of morphology cannot handle processes such as metathesis and, therefore, we must appeal to processual treatments.

On the other hand, it is unclear how one would deal with a phenomenon such as grammatically conditioned metathesis in a concatenative model of word formation that is limited to the use of structure-building operations and concatenation. Therefore, this type of problem is a crucial one in deciding the merits of either a processual or a concatenative model of morphology.

Webb (1974) represents an early attempt at dealing with metathesis, arguing that most cases are amenable to alternative analyses. Besnier (1987) provides an autosegmental account of the Rotuman case, and Stonham (1994) attempts to address the issue of metathesis and its reanalysis from the perspective of Lexical Phonology.

Since the motivation for the majority of cases of metathesis is the optimization of some structural aspect of the word, a constraint-based approach such as optimality theory (OT) would seem ideally suited to the analysis of this phenomenon (*see* **Pragmatics: Optimality Theory**). As Hock (1985: 533) puts it:

> Most commonly, the specific structural purpose of regular metathesis lies in converting phonologically or perceptually 'marked' structures into more acceptable ones.

One relevant OT constraint for metathesis is linearity, which is intended to ensure no variation in the sequence of segments, thus militating against metathesis. In the case of metathesis, linearity is not as highly ranked as competing forces. For a recent OT analysis of the Rotuman case discussed above, see McCarthy (2000).

Conclusion

Metathesis is not always the sporadic, irregular process that is often assumed. As demonstrated above, many instances involve regular, systematic use of metathesis to reconcile various ordering requirements within a language. The metathesis may be phonologically or grammatically conditioned and invariably produces a result that conforms to the requirements of the language.

Metatypy

M Ross, The Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Metatypy is a diachronic process in the course of which the syntax of one of the languages of a bilingual speech community is restructured on the model of the syntax of the speakers' other language. It is thus a language-contact phenomenon (*see* **Language Change and Language Contact**).

An Example: Takia

Takia, an Austronesian language (*see* **Austronesian Languages: Overview**) spoken on Karkar Island off the north coast of New Guinea, has undergone metatypy on the model of a nearby Papuan language of the Trans-New Guinea (TNG) family (*see* **Trans New Guinea Languages**).

Many Takia morphemes, both lexical and grammatical, are clearly cognate with those of Takia's Austronesian neighbors. These include Ronji, spoken about 100 km to the southeast. The Takia and Ronji examples that follow contain three cognate pairs: the independent pronouns Takia *ŋai* and Ronji *ŋa* 'I', the subject prefixes Takia *ŋ-* and Ronji *ŋa-*, and the verbs Takia *-ani* and Ronji *-ɣaŋ* 'eat' (the terms for 'banana' happen not to be cognate). The two languages differ sharply in their syntax, however. The Takia clause is Subject–Object–Verb, Ronji is Subject–Verb–Object; the Takia irrealis morpheme *wa* is an enclitic following the verb, while its Ronji counterpart *to* precedes the verb.

Takia:	ŋai	fud	ŋ-ani=wa
	I	*banana*	*1sing-eat=IRR*
	'I shall eat banana'		

Ronji:	ŋa	to	ŋa-ɣaŋ	saula
	I	*IRR*	*1sing-eat*	*banana*
	I shall eat banana'			

Takia and Ronji belong to the Oceanic subfamily of Austronesian, for which so much comparative evidence is available that it is certain that Ronji represents an inherited set of syntactic patterns. Takia syntax, on the other hand, reflects reshaping on the model of a TNG language. This remodeling is evident when we compare a Takia sentence with its equivalent in Waskia, a TNG language also spoken on Karkar Island. We cannot be absolutely certain that Waskia was the metatypic model for the reshaping of Takia, because there are many other TNG languages with similar syntax on the nearby mainland, but it is reasonably clear that Takia has copied its Subject–Object–Verb syntax from a TNG language. It is also likely that its postverbal aspect/mood enclitics are modeled on the suffixation of verbal markers in TNG languages.

Takia:	tamol	an	ŋai	i-fun-ag=da
	man	*DET*	*me*	*3sing-hit-me=IMPERF*
	'The man is hitting me.'			

Waskia:	kadi	mu	aga	umo-so
	man	*DET*	*me*	*hit-PRES.3sing*
	'The man is hitting me.'			

The Takia pattern of Noun + Determiner represented in the previous example by *tamol an* 'the man' probably also reflects restructuring on the model of a TNG language like Waskia, because Oceanic Austronesian languages typically have a Determiner + Noun construction.

Takia also displays massive lexical calquing ('loan translation'), apparently from Waskia. Examples like those in Table 1 can be easily multiplied.

Alongside lexical calquing, we find 'grammatical calquing,' i.e., reorganization or creation of closed categories such as adpositions or tense/aspect/mood markers to match Waskia. As part of its syntactic restructuring, Takia has lost its prepositions and calqued a set of postpositions which almost exactly

Table 1 Lexical calquing in Takia

	'Literal' meaning	*Takia*	*Waskia*
'animal'	'pig-dog'	bor-goun *pig-dog*	buruk-kasik *pig-dog*
'(do) first'	'his eye his eye'	mala-n-mala-n *eye-3sing-eye-3sing*	m<o>tam-m<o>tam *<3sing>eye-<3sing>eye*
'(an) answer'	'face of word'	ru nao-n *word face-3sing*	den k<o>ma *word <3sing>face*
'I disobey him'	'I cut his mouth'	awa-n ŋu-tale *mouth-3sing 1sing-cut*	k<u>riŋ batugar-sam *<3sing> mouth cut-1sing*

Table 2 Grammatical calquing: Takia postpositions

	Takia	*Waskia*
location	na, te	se, te, i
location 'in'	lo	nuŋi
location 'on'	fo, fufo	kuali
ablative	—	ko
instrument	nam (< na mi)	se
referential	o	ko
manner	mi	wam
accompaniment	da	karo

matches the Waskia set in its semantic organization (see Table 2).

As explained in the following sections, lexical and grammatical calquing are – strictly speaking – not components of metatypy; they are preconditions of it. Metatypy is just the reshaping of the syntactic system. This may (and typically does) take place without the borrowing of grammatical morphemes, as the Takia and Waskia examples show. See Ross (1987, 1996, 2001) on Takia metatypy.

Further Examples

Accounts of metatypy that provide sufficient detail for the reader to assess the overall process are few. Sasse (1985) describes how Arvanitic, the Albanian spoken in Greece, underwent lexical and grammatical calquing and syntactic change, increasingly resembling Greek. Soper (1996) describes metatypy in one Turkic and one Iranian language, each on the model of a language from the other family. Aikhenvald (2002) gives a thorough account of grammatical calquing and metatypy in Tariana (Tariano), an Arawak language, on the model of East Tucanoan languages. Various authors, listed by Harris and Campbell (1995: 124, 142), have investigated the metatypy of Ethiopian Semitic languages on Cushitic models.

Defining Metatypy

None of these authors uses the the term 'metatypy,' which was coined by Ross (1996) to label the historical process briefly illustrated in the example for Takia: a reshaping of the syntactic system of one of a bilingual community's languages so that it more closely resembles the syntax of its speakers' other language. Metatypy means 'change in type' (just as metamorphy means 'change in form' in geology). 'Type' is used here in the sense implicit in the term 'typology': Subject–Object–Verb and Subject–Verb–Object are clause 'types,' Noun + Determiner and Determiner + Noun are noun phrase 'types.'

This definition is narrower than the one used by Ross (1996, 1997, 2001, 2003). In these works, metatypy was treated as also including lexical and grammatical calquing. This was done because contact-induced syntactic restructuring of the kind outlined earlier in this article is apparently always accompanied by lexical and grammatical calquing. Further research supports a claim by Sasse (1985: 79) and Ross (2001: 146) that lexical and grammatical calquing **precede** syntactic restructuring, i.e., they are preconditions of syntactic restructuring. Because there are cases where widespread grammatical calquing has occurred, but little or no syntactic restructuring (e.g., the Mixe dialect of Basque described by Haase (1992), where there is extensive grammatical calquing on Gascon, but only limited syntactic restructuring), it is appropriate to treat grammatical calquing and syntactic restructuring as separate processes and to reserve the term 'metatypy' for the latter, because this is the locus of the 'change in type.'

The process of metatypy was recognized by scholars long before the term was coined. For example, it was inferred that the parallel syntactic systems of Balkan languages (*see* **Balkans as a Linguistic Area**) were the result of syntactic remodelling (Sandfeld, 1930; Joseph, 1983). Gumperz (1969) and Gumperz and Wilson (1971) describe the situation at Kupwar, an Indian village on the Indo-Aryan/Dravidian border, where the local varieties of (Indo European) Marathi and Urdu have undergone radical restructuring on the model of (Dravidian) Kannada. Arvantic was mentioned above. The Arabic of Maronite Christians in Cyprus, which has undergone reshaping along Cypriot Greek lines, has attracted scholarly attention (Newton, 1964; Newton, 1972; Tsiapera, 1969). The syntax of the Rhaeto-Romance (Romansch) dialects of Switzerland has become more like German (Haiman, 1988). These are all instances of metatypy.

Other labels have been used for metatypy, but none is fully satisfactory. Appel and Muysken (1987: 158) use 'resyntactization,' but it is unclear whether this is intended to denote the replacement of single constructions or system-wide restructuring.

Sasse, Aikhenvald, and others use the term 'convergence,' but this is unfortunate on two counts. First, it seems sometimes to cover lexicon, morphology and/or phonology as well as syntax. Second, 'convergence' implies that both languages change simultaneously, each in the direction of the other, until their structures meet somewhere in the middle. There is little documentation of this. Takia has changed, but Waskia has not. Arvanitic and Maronite Arabic have changed, but not Greek. (A more appropriate context for the term 'convergence' is koineization, where dialects or closely related languages spoken in a newly forged speech community become increasingly similar until a single common language emerges. This

is quite different from metatypy, where the two languages are typically unrelated, one becomes more similar to the other, and no common language emerges.)

Another term that has been used for metatypy is 'structural borrowing.' Thomason and Kaufman (1988: 67) note that where there is 'intense contact,' i.e., widespread bilingualism, structural borrowing occurs. But the term 'structural borrowing' is inappropriate for three reasons. First, it is not simply structure that is copied, but a pairing of structure and meaning. Second, 'borrowing' implies sporadic, piecemeal changes, whereas metatypy is usually a system-wide process, a distinction also noted by Soper (1996: 295). There is a strong tendency in the literature to remark on isolated contact phenomena without giving their linguistic context, thereby creating the impression that piecemeal 'structural borrowing' is more common than it is. Third, Prince (1998) provides evidence from her study of the restructuring of Eastern Yiddish on Slavic models that speakers often do not necessarily 'borrow' constructions wholesale but instead exploit the possibilities of constructions in the language undergoing metatypy (she does not use the term) to imitate those of the model language with varying degrees of exactness. The Mixe Basque passive, for example, is an extension of the Basque resultative, which imitates the Gascon passive but is structurally unlike it (Haase, 1992: 101–102).

The Process of Metatypy

Sasse (1985: 84–85) proposes that lexical calquing, grammatical calquing, and syntactic restructuring share a single cause: bilingual speakers' need to express the same thoughts in two languages. Haase (1992: 166–168) talks of a push toward 'translation equivalence.' The inference is that lexical calquing takes place first as speakers reorganize the lexicon of one of their languages to match the semantic organization of the other. This reorganization extends to closed categories, so that grammatical calquing also occurs. Only when the categories of the two languages match each other closely does syntactic restructuring begin.

Calquing and metatypy are both dependent on the fact that a language is made up of form–meaning pairings. These include both lexical items and grammatical constructions. The form component of a grammatical construction is typically a combination of syntactic structure and certain morphemes. The meaning component is often quite abstract, and so the sequence of lexical calquing > grammatical calquing > metatypy is one in which forms that express increasingly abstract and general meanings come to be organized similarly in the two languages.

Two points are noteworthy here. First, as the Takia–Waskia examples show, calquing does not entail borrowing of form but reorganization of the way existing phonological forms match meanings. Second, because the form component of a grammatical construction often consists partly of syntactic structure, metatypy differs from calquing (where form may be unchanged) in that the structure itself is altered in the course of the push toward translation equivalence. Although this account is intuitively satisfying, it is not clear what triggers the move from calquing to metatypy, because some languages do not undergo metatypy or do so only to a limited extent. Mixe Basque, for example, has undergone extensive grammatical calquing but little metatypy. Is this because of quantitative or qualitative differences between the grammars of Basque and Gascon? We do not yet know. (For discussion, see Harris and Campbell, 1995: 123–127.)

Metatypy occurs in a three-stage sequence. The clause is restructured first, then the phrase, and finally the word, but this sequence is rarely completed. Anem, a Papuan language of New Britain, reflects restructuring of the clause only (on an Austronesian model; Ross, 2001). Takia reflects restructuring of the clause and the phrase. The languages at Kupwar reflect reorganization of clause, phrase, and word-internal morphemic structures. Outcomes that do not follow this sequence, e.g., the restructuring of the phrase but not the clause, have not been found. Metatypy has been described here as **syntactic** restructuring, but, as at Kupwar, syntax may also include the ordering of bound morphemes.

The Boundaries of Metatypy

The boundaries of metatypy need to be delineated in a number of dimensions. In Ross (1995, 2001, and particularly 2003: 190), a further social criterion for metatypy is given: the language undergoing metatypy will be the language that is emblematic of its speakers' identity and the metatypic model will be the language used to communicate with another speech community. This is true of the majority of cases found, but not of all. Sometimes the social relationship between the languages is the opposite one: the language undergoing metatypy is the inter-community language, and the metatypic model is its speakers' emblematic language. Cases in point are 'Singlish' (basilectal Singapore English; Platt, 1975) and Taiwan Mandarin (Chappell, 2001). The key here is that these are spoken in speech communities where speakers of the emblematic language are a significant majority and where a variety of the inter-community language

is used at least as much for communication among those speakers as it is for communication with speakers of another language.

Metatypy sometimes appears to be accompanied by contact-induced phonological changes, e.g., in Tsat, the Austronesian language of Hainan Island that has undergone metatypy on the model of Chinese dialects and, like them, has also become monosyllabic and tonal (Thurgood and Li, 2003). Sasse (1985) suggests that such phonological change **follows** metatypy. A number of the cases of metatypy mentioned here display no such change, and this implies that contact-induced phonological change does not usually occur until metatypy is well progressed. Cases like Singlish, where the inter-community language undergoes metatypy, are exceptions: here, phonological accommodation to the emblematic language may be part of the creation of the new variety.

Theoretical Issues

The study of metatypy touches on a number of theoretical issues in historical linguistics. One is that there is an emerging paradigm of types of contact-induced change, according to which social conditions constrain the linguistic outcomes of contact (Thomason and Kaufman, 1988; Ross, 1997; Ross, 2003). Metatypy is only one such outcome. Language shift, pidginization, and language mixing are others (*see* **Language Maintenance and Shift**).

Genealogical relationships among languages are often expressed through the family-tree model (*see* **Language Families and Linguistic Diversity**), which presupposes language continuity from generation to generation. This continuity is not disrupted by metatypy, and continuing lexical forms and bound morphemes bear witness to this. Thomason and Kaufman (1988: 83–97) discuss the fact that 'structural borrowing,' i.e., metatypy, involving a number of contiguous languages leads to the formation of a Sprachbund or 'linguistic area.' A question in the case of, say, the Balkan Sprachbund, is whether there has been gradual convergence among its languages or a sequence of bilingual situations in which (unilateral) metatypy has occurred. This requires further investigation.

Unresolved questions are whether and under what circumstances languages 'borrow' single constructions rather than making system-wide changes (Harris and Campbell, 1995: 120–150).

Other Cases of Metatypy

As well as the works mentioned earlier in this article, the following contain reports on cases of metatypy: Denison (1968, 1977, 1988) on Sauris, a German dialect of northern Italy; Haig (1988) on East Anatolia; Heine and Kuteva (2001) on African languages; Nurse (1994) on Ilwana, a Bantu language (Malakote) remodelled on Orma, a Cushitic language; and Thurgood (1999) on Austronesian Chamic languages.

Meter is a poetic form defined by constraints on the rhythmic structure of language, giving the language of metrical texts a rhythmic regularity beyond the usual rhythm of the language in which they are composed. Meter therefore involves language and linguistics in at least two ways. One is a matter of descriptive necessity: the rhythmic structure of language must be described in a way that allows the constraints that define a meter to be stated – to take a simple example, a meter that requires a specific number of syllables requires in turn a notion of the syllable, which is itself a linguistic entity, and not a specifically poetic one, let alone one belonging to another domain of experience entirely. The other is a matter of theoretical inquiry: are the constraints that define meters themselves a matter of linguistic form, even if the language they define is a special kind of language we call 'poetry,' or more accurately, 'verse'; or are they something else entirely, a set of structures composed of language but according to principles that diverge from whatever may be the constitutive principles of language itself?

The fundamental methodological assumption through which both questions have been investigated within linguistics over the past few decades also derives from linguistics, though it does not on its own presuppose answers of one kind or another to the questions above. Following closely on Chomsky's (1965) observation that a description of a language should be generative in the sense that it should describe not the set of actual utterances in the language, but its speakers' competence, the intuitive knowledge lying behind those utterances through which speakers recognize that some forms count as well-formed instances of their language while others would not, Halle and Keyser (1966, 1971) proposed that a description of a meter should be held to the same standard. A poet composing in a meter has intuitions about what arrangements of the language would be well-formed in the meter and what would not, and a

Meter is a poetic form defined by constraints on the rhythmic structure of language, giving the language of metrical texts a rhythmic regularity beyond the usual rhythm of the language in which they are composed. Meter therefore involves language and linguistics in at least two ways. One is a matter of descriptive necessity: the rhythmic structure of language must be described in a way that allows the constraints that define a meter to be stated – to take a simple example, a meter that requires a specific number of syllables requires in turn a notion of the syllable, which is itself a linguistic entity, and not a specifically poetic one, let alone one belonging to another domain of experience entirely. The other is a matter of theoretical inquiry: are the constraints that define meters themselves a matter of linguistic form, even if the language they define is a special kind of language we call 'poetry,' or more accurately, 'verse'; or are they something else entirely, a set of structures composed of language but according to principles that diverge from whatever may be the constitutive principles of language itself?

The fundamental methodological assumption through which both questions have been investigated within linguistics over the past few decades also derives from linguistics, though it does not on its own presuppose answers of one kind or another to the questions above. Following closely on Chomsky's (1965) observation that a description of a language should be generative in the sense that it should describe not the set of actual utterances in the language, but its speakers' competence, the intuitive knowledge lying behind those utterances through which speakers recognize that some forms count as well-formed instances of their language while others would not, Halle and Keyser (1966, 1971) proposed that a description of a meter should be held to the same standard. A poet composing in a meter has intuitions about what arrangements of the language would be well-formed in the meter and what would not, and a

description of the meter should make those intuitions explicit. Traditional descriptions often do not achieve this because they focus on describing the rhythmic structures that actually occur in poets' compositions, without distinguishing them from those that could not have occurred to arrive at the meter's generative principles.

For example, the English iambic pentameter is often defined as having a basic line of five iambic feet (separated in scansion by '|'), each composed of two syllables that rise in stress; in many accounts, the rise is the only requirement (Steele, 1999; Wimsatt and Beardsley, 1959; Wimsatt, 1970), while in others the basic foot is held to be specifically an unstressed syllable (x) followed by a stressed one (/) (Fussell, 1979; Stallworthy, 1983). Variant feet composed of one or three syllables, or of syllables that fall or remain level in stress (anapests, trochees, dactyls, spondees, pyrrhics, etc.), are sometimes used instead of the basic iambic foot for aesthetic variety and expressive effect. Both the basic pattern and some of its variants can be seen, for example, in Tennyson's 'The Kraken' in (1), composed of fourteen lines of iambic pentameter plus a longer fifteenth line:

(1) Below the thunders of the upper deep,
Far, far beneath in the abysmal sea,
His ancient, dreamless, uninvaded sleep
The Kraken sleepeth: faintest sunlights flee
About his shadowy sides; above him swell 5
Huge sponges of millennial growth and height;
And far away into the sickly light,
From many a wondrous grot and secret cell
Unnumber'd and enormous polypi
Winnow with giant arms the slumbering 10 green.
There he hath lain for ages and will lie
Battening upon huge sea-worms in his sleep,
Until the latter fire shall heat the deep
Then once by man and angels to be seen,
In roaring he shall rise and on the surface die. 15

Line 3, for example, has five feet with the basic structure as shown in (2a), but as shown in (2b), line 12 begins with a foot that has a fall in stress plus an extra syllable, with other complexities following, such as a succession of four stressed syllables, all contributing to the description of the uncontainable otherworldly enormity of the sea monster:

(2a) x / | x / | x / |x / |x /
His ancient, dreamless, uninvaded sleep
/ x x | x /| / / | / x | x /
(2b) Battening upon huge sea-worms in his sleep,

This description of the iambic pentameter of 'The Kraken,' however useful for identifying interesting rhythmic structures in particular lines of the poem, is, however, inadequate as an account of what makes the general rhythmic structure of its metrical language distinct from that of ordinary English. The problem, as Halle and Keyser pointed out, is that the statement of what variations on the basic pattern can occur is insufficiently constrained: any text of English (or indeed any other language) can be divided up into lines composed of successions of two but sometimes three syllables, normally with a rise in stress but sometimes with a fall or no change; but among those lines would be some with rhythmic structures that never occur in iambic pentameter, either in general or in the practice of specific poets in specific genres. The line produced in (3), for example, by replacing 'uninvaded' in line 3 of 'The Kraken' with "unvariable," can be represented as having five feet, one of which has falling stress and an extra syllable just as the language of line 6 does:

(3) x / |x / | x / | /xx|x /
*His ancient, dreamless, unvariable sleep

But (3), in having the exceptional foot begin not only mid-line but mid-word, has a structure that Tennyson does not use in this or any other iambic pentameter poem, while line 3 in (2b) is a line he actually wrote in that meter. Hence, the traditional description fails to capture what would seem to be Tennyson's intuitions about what makes some language iambic pentameter – what distinguishes metrical from unmetrical lines. The claim that a line has a structure that could not be used in a given metrical form is a claim that it is unmetrical, indicated by the same asterisk used to indicate ungrammaticality in ordinary language.

Of course, one of the difficulties faced by any attempt to achieve this standard of a generative description of a metrical form is that it is impossible to inquire directly into the poet's intuitions; all we have is evidence of what actually has been composed. In this, as Rice (1996) pointed out, metrics resembles internal reconstruction in historical linguistics, in that the system that defines some grammatical competence must be hypothesized solely on the basis of a finite corpus, and whether a structure's nonoccurrence is actually a matter of systematic avoidance on grounds of its ill-formedness – here unmetricality – or merely accidental, is always a matter of judgment. Moreover, because meter is not simply a naturally occurring part of language but an art form, with structures created for specific expressive effects, there is always an intermediate possibility that a structure would be well-formed but not create just the right effects in its particular context. These considerations apply equally to the interpretation of

counterexamples to any hypothesized description of a meter: a line that does not conform to it might reflect anything from corrupt transmission of a text to deliberate departure from the metrical form or a missed generalization in the description. And because poets are often as interested in innovation as they are in perpetuation of a tradition, a deliberate departure might be an unmetrical line, but it might also be a line that slightly revises what qualifies as metrical to define a new possibility within the tradition.

In spite of these complexities, understanding of meter has made enormous strides in the past few decades. This is not only a result of the level of attention to small details and their large consequences following from Halle and Keyser's descriptive challenge, but perhaps even more importantly because of the enormous strides made in the description of linguistic rhythm itself. In the past, metrists almost always had to invent their own systems to represent the rhythmic structures of lines they wished to discuss, because linguistic descriptions were either too impoverished to express the full range of rhythmic structures used in poems or too complex to express the essential simplicity inherent in the sense that meters increase rather than decrease regularity. Moreover, such inventions were often unavoidably subjective, tied to interpretations of poems and to assumptions about what would be appropriate performances of them. Liberman and Prince's (1977) fundamental insight that linguistic rhythm was different from other aspects of phonology gave a simple set of principles from which to represent a wide and subtle variety of rhythmic structures. In practical terms, their approach inspired fruitful crosslinguistic research into the phonology of rhythm, the articulation of an explicit theory of the principles of that phonology, and the discovery of a rich range of structures that play a role in it. This theory and its claims, even while its particulars are debated, have gone a long way toward providing metrics with descriptive mechanisms that are objective at least in the sense of being shared by a scholarly community and established on independent grounds for articulating the complex textures achieved in actual poems.

But what is especially interesting for meter is that particular characteristics of Liberman and Prince's approach make it simultaneously up to the task of illuminating the simple sense of regularity generally felt to be created by meter. The key insight is that all language has a rhythmic structure that is in fundamental ways similar to the rhythmic structure of music or other rhythmic activities in being relative, periodic, hierarchical, and culminative. The basic structural elements that create these properties are, roughly speaking, (1) some kind of regular beat that keeps time; (2) differentiation in prominence among those beats, so that some are strong and others are weak; and (3) grouping of beats according to that differentiation, so that each strong beat defines a group of its own which may also include weak ones. These rhythmic groups are themselves organized at higher levels according to the same principles, right on up to the point where an entire domain has been rhythmically organized. To take a very simple example, four beats might be organized rhythmically into a duple, falling scheme at every level, as in (4a), with the first strong beat being stronger than the second one, because the group it defines is stronger at the next level up. This is the stress pattern of a word like, for example, *úndertàker*, as shown in (4b), which has primary stress (´) on its first syllable and secondary stress (`) on its third, and a rhythmic boundary between its second and third syllables strong enough to admit word-internal expletives there (*under-fuckin'-taker* but not **un-fuckin'-dertaker* or **underta-fuckin'-ker*):

(4a)

(4b)

where 'S' represents a rhythmically strong element and 'W' a rhythmically weak one. As discussed elsewhere in this volume (*see* **Metrical Phonology**), the study of linguistic rhythm has in general pursued questions of what exactly are the beats in language (syllables [σ], or some lower level like moras [μ], etc.); the higher levels of organization (phonological feet [ϕ], phonological words [ω], etc.); the principles of grouping (binary [duple], ternary [triple] etc.; rising, falling, etc.); the strategies for dealing with odd numbers of elements that may leave some not fitting into the parse (deletion, adjunction, etc.); – all with the goal of being able to describe the stress systems of all the world's languages through a constrained universal set of formal devices.

For meter, one application of this theory that has proved particularly fruitful has been the assumption that, rather than specifying particular arrangements of linguistic elements at the level of specificity in (4b), what at least some meters do is define a template for a general rhythmic structure, more like that in (4a), together with a set of correspondence rules that govern how specific properties of linguistic structures like that in (4b) can be mapped into the template. For iambic pentameter, for example, the meter of the first 14 lines of example (1), the template has been argued to be that in (5), consisting of five rising feet, each composed of a weak position (W) followed by a

strong one (S), with these feet grouped in their turn ambiguously into two rising cola, which are grouped finally into a line (Halle and Keyser, 1966, 1971; Kiparsky, 1977; Prince, 1989; Piera, 1981).

Because the correspondence rules will regulate mapping into this template of some rhythmic properties of a text but not all, this approach allows the full complexity of the actual rhythmic structure of any line to be acknowledged at the same time that the simplicity of the basic rhythm is represented in the template. Specific artistic effects may be seen to be achieved by the interactions between these two levels of representation, as the actual rhythmic structure of the language meets or – especially in the case of unregulated aspects of that structure – does not meet expectations represented by the template, a dynamic that, however it is modeled, is at the heart of virtually every account of the expressive power of meter as a poetic form (Attridge, 1982, 1995; Cureton, 1992; Hollander, 1989; Wright, 1988).

In what follows, drawing on a typology of meters particularly closely modeled on linguistic rhythm (Hanson and Kiparsky, 1996), I will show how this general approach can describe several traditional meters of modern English in ways that begin to meet Halle and Keyser's descriptive challenge. At the same time, however, it will be seen that many questions remain open as to the exact interaction of these descriptions with ever-evolving models of linguistic rhythm.

All illustrations are drawn from the practice of Alfred Lord Tennyson, a poet especially renowned for his metrical accomplishment.

Stress

Stress in English Iambic Pentameter

To return to the iambic pentameter of (1), one claim that is fairly well agreed upon is that it regulates rhythmic prominence specifically by constraining the placement of (to simplify briefly for a moment) stressed syllables of polysyllabic lexical words; such syllables must be mapped into strong positions, not weak ones (Kiparsky, 1975, 1977). Setting aside for a moment the question of the extra syllable of the unmetrical line in (3), it is thus the placement of the stressed syllable-*va*-of of *unvariable* in W as in (6b) which renders the line unmetrical, compared to the well-formed placement of the stressed syllable of *uninvaded* in S in the original metrical line scanned in (6a):

(6a) His áncient, dréamless, ùninváded sleep
w s w s w s w s w s

(6b) *His áncient, dréamless, ùnvárìable sleep
w s w s w s *w s w s

What is interesting here from a linguistic point of view is how this one type of stress has been singled out from the many types of stress that language in fact makes available. There are, for example, contrasts between unstressed and stressed syllables in an absolute sense, measured by the ability of unstressed syllables to tolerate schwa ([ə]) as their only vowel, as in, say, the second, fourth, and fifth syllables of *mètropólitan*, as opposed to the first and third, which must have full vowels with distinct qualities. There are contrasts between primary and secondary stress; even if both the first and third syllables of *mètropólitan* have some stress, that of the first is noticeably less than that of the third. Similarly, in a word like *màintáin*, both syllables have some stress, but the second has more than the first (in contrast to a word like *detáin,* in which the second has more than the first, but the first can have no stress at all). Similarly, there are distinctions between compound stress, in which two words, each already with some stress, are joined together with more stress on the first to make a new word, as in *blúebìrd*, and phrasal stress, which in English also involves the imposition of a characteristic stress pattern on a pair of already stressed words, but with greater stress on the final word, so that in a sentence like *I saw some blùe bírds*, *birds* will have more stress than *blue*, unless a reading contrasting blue birds with birds of another color is intended. And there are rather more abstract distinctions in stress, involving the fact that certain classes of words, such as nouns, verbs, and adjectives, require stress, while other grammatical classes of words do not, being free to be stressed or not depending on their phrasal context and rhetorical import; thus the conjunction *but* may be stressed ([bʌt]) or unstressed ([bət]), but the verb *butt* must always be stressed ([bʌt]).

The question for metrics, then, has been exactly which among these rhythmic contrasts in language is actually regulated in the English iambic pentameter. As Halle and Keyser observed, there seem to be no constraints on strong positions in the English iambic pentameter: they are perfectly free to include syllables with no stress at all. And weak positions can contain syllables with some stress: in line 12 repeated in (2b), for example, some of the syllables in the phrase *upon huge sea-worms* are going to have to be in W even though stressed. Weak positions can even include the strongest stress of a phrase, as in *stream* in (7):

(7) Between the loud stream and the trembling stars
w s w s w s w s w s
('Oenone,' 215)

But as Kiparsky (1975) argued, what is common to these cases of stressed syllables in W is that they are monosyllabic words; stressed syllables of polysyllabic words do not have this freedom, and it is this fundamental constraint on their occurrence in W that *unvariable* violates in (6b), making the line unmetrical.

Even as this generalization is broadly accepted in its rough form, however, there has been significant debate as to its exact formulation. Assessing which representations of English stress best capture it (Kiparsky, 1977; Hayes, 1983; Hanson and Kiparsky, 1996; Fabb, 2002); modeling its interaction with other constraints to produce variation across individual poets' practice (Kiparsky, 1977; Hayes, 1983); adducing and incorporating counterexamples (Youmans, 1983; Golston, 1998); and other challenges all suggest that the description of such a core characteristic of even this familiar meter is by no means completely settled.

Inversion

One of the core sets of counterexamples that any account of English iambic pentameter must address is the configuration traditionally called 'inversion,' illustrated by *battening* in line 12 of (1), scanned in (8a) (again temporarily setting aside discussion of the line's extra syllable), and also by *winnow* in line 10 of (1). In these lines, the constraint against stressed syllables of polysyllabic words in W is violated in the first position of the line, in a practice common to all English poets. Violations also occur line-internally, with varying degrees of frequency and disruption, as in *cities* in (8b):

(8a) Báttening upon huge sea-worms in his sleep,
w s w s w s w s w s

(8b) Much have I seen and known -- cities of men
w s w s w s w s w s
('Ulysses,' 13)

However, these violations have been shown to be systematic in their own right: roughly, again, they are allowed just in case the stressed syllable follows a break, and thus initiates a new phrase (Jespersen, 1922; Halle and Keyser, 1971; Kiparsky, 1975, 1977; Hayes, 1989). However, here, too, the exact formulation of just what kind of a break across different poets' practice has raised a number of interesting linguistic questions – Hayes (1989), for example, showed that the relevant phrasing is phonological, not syntactic, and also hierarchically organized, with inversions after fairly low-level boundaries being allowed only if they are also allowed after high-level ones, so that some conservative poets, for example, might allow only the latter. Another open interesting question involves just how inversion interacts with the metrical hierarchy of the organization of feet into cola, lines, etc.

Grammatical Words

A final example of an interesting question about linguistic organization relevant to metrical practice is the status of stress on grammatical words. The exclusion of stressed syllables of polysyllabic words from W unless they initiate a new phrase of some level is followed much less strictly for prepositions, conjunctions, auxiliaries, pronouns, etc., than it is for nouns, verbs, or adjectives by virtually all English poets. The placement of the stressed initial syllable of the preposition *into* in line 7 of (1), scanned in (9a), affords an example, but does not prove the point since it also initiates a new phrase; grammatical words whose second syllable is stressed, however, and so cannot initiate a new phrase, are likewise occasionally positioned with that syllable in W as is the preposition *upon* in (9b).

(9a) And far awáy ín to the síckly light,
w s w s w s w s w s
(9b) Like footsteps upón wool. I dímly see
w s w s w s w s w s
('Oenone,' 246)

Halle and Keyser (1966) had observed in their initial study of Chaucer that in general the stress of grammatical words seemed irrelevant to metrical well-formedness. The generalization seems true, even if the freedoms it affords are indulged with varying frequency by different poets; and the question therefore remains for linguistics exactly why that should be so (Kiparsky, 1975, 1977; Hayes, 1989; Hanson, forthcoming). What is interesting is that there is ample evidence that in ordinary language there are also significant formal differences in the nature of stress on grammatical words as opposed to others (Selkirk, 1995).

Syllable Count

Elision and Diaeresis

The other basic rule of much English iambic pentameter illustrated by 'The Kraken' is that there is a single syllable in each metrical position. As mentioned above, this raises the linguistic question of exactly what is a syllable. Since the syllable is a comparatively familiar linguistic entity, the answer may seem obvious; but it is not so obvious for poets, as it is

not for linguists. Rather, the English iambic pentameter is like virtually all meters in incorporating rather elaborate possibilities for elision and diaeresis – reductions of two adjacent syllables to one for purposes of metrical syllable count, or expansion of one into two, respectively – and description of the rules governing such practices and contemplation of their limits provide an interesting window on the question of what exactly are possible syllables.

Building on Tarlinskaja (1976) and others, Kiparsky (1977) identifies three basic rules of elision in English iambic pentameter, conventionally annotated by a slur '‿'. One, illustrated in line 6 of 'The Kraken' and scanned in (10a), allows an unstressed high vowel (here [i]) followed by another unstressed vowel to be treated as a glide, and hence allows the whole sequence to be treated as a single syllable. (This rule is what accommodates the extra syllable of *unvariable* in (6b), but it cannot rescue the line from its problematic stress placement.) Sequences of this type involving separate grammatical words can be elided in the same way, as in (10b) (as can sequences involving the other high vowel of English ([u]) as in words like *influence*, or phrases like *to embrace*):

(10a) Huge spónges of millénnial growth and height;
w s w s w s w‿ s w s

(10b) And áfter mány a súmmer dies the swan
w s w s w‿ s w s w s
('Tithonus,' 4)

Another rule of elision allows an unstressed vowel followed by a single sonorant consonant ([n, m, ŋ, r, l, w, j]) and then another unstressed vowel to be deleted, as in the elision of *battening* from line 12 of 'The Kraken,' scanned in (8a) above, or *slumbering* from line 10 scanned in (11):

(11) Wínnow with gíant arms the slúmbering green.
w s w s w s w s w‿ s

A final rule of elision allows any two adjacent vowels to count as a single syllable, as in (12):

(12) Of happy men that have the power to die
w s w s w s w s‿ w s
('Tithonus,' 70)

As Kiparsky (1977) argued, these rules can be seen to be plausible phonological reductions partly because they are actual phonological reductions in many English dialects. What is interesting, however, is that they cannot be assumed to simply reflect actual reductions in the poet's dialect, because they are optional. In (13), for example, in *shuddering,* exactly the same type of sequence that is read as one syllable in (11) is read as two:

(13) Reel, bruised and butted with the shuddering
w s w s w s w s w s
('Tiresias,' 97)

Rather, they represent a more abstract notion of a possible English syllable, as if that is a notion the poet is using the meter to explore. The question of what range of elisions poets use in particular languages and also universally is thus of interest to the theory of syllable structure in general.

Syllable count in English iambic pentameter also poses a few historical puzzles that remain unsolved. The word *heaven* is treated as if it has a monosyllabic variant, as in (14), in virtually every English poet's practice:

(14) From me, heaven‿'s queen, Paris, to thee king-born
w s w s ws w s w s
('Oenone,' 125)

Other words that behave similarly and have similar phonological structures include *even, ever, over,* and *devil*. Since some of these have monosyllabic variants either in poetic notation (*e'en*) or regional dialects (*de'el*), it has been argued that the practices might have their origins in reductions that were phonologically plausible for forms of these words now lost, perhaps having, for example, a glide where we now have [v] (Kökeritz, 1953); but the question remains open, and the words stand as a testimony to the possibility of conventions persisting in poetic practice even when they cease to be grounded in the language.

In a similar way, another familiar poetic practice can recuperate a syllable from a suffix that no longer constitutes one in the ordinary language, as in *aged* in (15a). And finally, the English iambic pentameter sometimes also exhibits hiatus, the reverse of elisions of the type in (12), in the counting of two adjacent vowels that might well be considered a single syllable in the ordinary language as two for purposes of the meter, as in *cruel* in (15b):

(15a) Match'd with an aged wife, I mete and dole
w s w s w s w s w s
('Ulysses,' 3)

(15b) Me only cruel immortality
w s w s w s w sws
('Tithonus,' 5)

Extrametricality and Catalexis

The foregoing complications in syllable count are akin to the earlier-discussed question of the treatment of the stress of grammatical words, in that they involve questions of what the linguistic representation of the language to be mapped into the template looks like – whether it is like or unlike the ordinary

language, and how and why. There is another complication in syllable count even for this simplest form of the English iambic pentameter, however, that is more like the question of inversions discussed above, in involving an exceptional mapping of that language into the template. It is a completely familiar characteristic of the English iambic pentameter for some lines to have what is sometimes called a 'feminine ending,' an unstressed syllable at the end of the line in excess of the usual ten. These syllables have been analyzed as exactly analogous to extrametrical syllables in language, in being peripheral constituents that simply remain outside of a basic rhythmic parse, and in fact were the inspiration for that crucial component of the theory of the phonology of rhythm (Hayes, 1988). Hence, they are normally referred to by linguists as 'extrametrical' and notated by the same angled brackets ('<>') used for extrametricality in language, as in (16):

(16) O móther Ida, mány fóuntain'd Ida
w s w sw s w s w s<>
('Oenone,' 33)

Extrametrical syllables are in many ways analogous to the inversions discussed earlier, except for being a phenomenon special to ends rather than to beginnings. It comes as no surprise, then, that just as inversions are possible within lines at the beginnings of phrases, so extrametrical syllables are possible within lines at the ends of phrases, as in (17), raising the same issues as to exactly where they are allowed and why, and in particular how the phenomenon interacts with phrasing:

(17) Unbías'd by self-prófit, O, rest thee sure
w s w s w s <> w s w s
('Oenone,' 156)

Still another complication in syllable count is, like these phenomena, confined to edges – beginnings or ends, as we will see, depending on the meter – and interacts with extrametricality to give one of the most traditionally vexing issues in metrics. It is well known that during certain periods especially, English poets have occasionally allowed an initial syllable to be missing from an iambic line, as in the line from Chaucer in (18) cited by Halle and Keyser (1971) to illustrate this possibility:

(18) ø Twenty bookes, clad in blak or reed
w s w s w s w s w s
(*The Canterbury Tales*, 'General Prologue,' I 294)

In English, such lines have sometimes been called 'headless' and sometimes 'catalectic.' Interestingly, Kiparsky (1993) argued that the metrical practice has an analog in language just as much as extrametricality does, in that languages sometimes treat a syllable as present for purposes of a rhythmic parse even though it has no segmental manifestation, just as under extrametricality they sometimes treat one as absent even though it has segmental manifestation; the phonological possibility was developed extensively for English by Burzio (1994) but has not been nearly so thoroughly explored cross-linguistically as extrametricality has.

What is problematic for meter if these phonological suggestions are correct, then, is not the existence of the catalexis, but rather the way it interacts with extrametricality to confuse the very issue of what template a meter has. Catalexis is not especially common in English iambic meter – as noted by Young (1928), it serves the same function as inversion of allowing a line to begin with a stress and went out of fashion as that came in. But in trochaic meter, it is the norm for the final weak position to go unfilled by any syllable, as illustrated by Tennyson's short poem 'Home they Brought her Warrior Dead' in (19):

(19) Home they brought her warrior dead;
She nor swoon'd nor utter'd cry.
All her maidens, watching, said,
"She must weep or she will die."
Then they praised him, soft and low, 5
Call'd him worthy to be loved,
Truest friend and noblest foe;
Yet she neither spoke nor moved.
Stole a maiden from her place,
Lightly to the warrior stept, 10
Took the face-cloth from the face;
Yet she neither moved nor wept.
Rose a nurse of ninety years,
Set his child upon her knee,
Like summer tempest came her tears – 15
"Sweet my child, I live for thee."

The first line is scanned in (20a) as trochaic tetrameter, assuming the same correspondence rules as for iambic pentameter but a different template, and line-final catalexis:

(20a) Home they brought her warrior deadl Ø
s w s w s w s w
(20b) Like summer tempest came her tears – Ø
<> s w s ws w s w

The problem is that if this poem is indeed trochaic, then line 15 shows that trochaic meter must admit extrametrical syllables initially, as represented in the scansion in (20b). From a formal point of view, if iambic meter allows catalexis initially and extrametricality finally, it is entirely to be expected that trochaic meter should allow catalexis finally and extrametricality initially. The consequence of this, however, is that, as Saintsbury (1906) observed, it

becomes possible to scan any iambic line as trochaic or vice versa using these devices; the lines in (20) could equally be as in (21):

(21a) ø Home they brought her warrior dead;
w s w s w s w s

(21b) Like summer tempest came her tears –
w s w s w s w s

This ambiguity has been used to argue that English meter is defined only by a fixed number of beats (Wallace, 1996). However, this conclusion misses the artistry with which this ambiguity is exploited by poets: on the model of English meter developed here – itself based on the model of linguistic rhythm as a complex hierarchical structure – the analysis of a line as iambic or trochaic is not just a question of whether one starts with a weak or a strong position, but entails a complex hierarchical organization of those positions, as, for example, in (5), defining precise positions for boundaries of metrical units like feet, cola, and lines as well as precise positions for which syllables may be extra or missing, all of which define expectations that the language of a line may fulfill, challenge, or disappoint in some way. Which is the right template in a particular poem may not be decided on linguistic grounds, but it is not without interpretive consequences; for example, on the scansion in (20b), line 11 might be seen as especially tumultuous, with its unincorporable extra syllable, whereas on that in (21b) it can be seen as coming as a relief, in that something missing has been restored. Or in Tennyson's 'The Lady of Shalott,' the example of the problem famously discussed by Saintsbury (1906), the inability to get one's metrical bearings is part of what makes the poem seem to waver between what is real and what is imagined, an effect that would be inexplicable if a line simply had a fixed number of beats and no other structure.

Resolution

Another traditional observation about English meters that has received a rather new interpretation as a result of developments in linguistics is that extra syllables sometimes occur in positions where they can be neither elided nor understood as extrametrical. Lines like those in (22), if they are to be mapped into an iambic pentameter template like that in (5) as other lines in the poems they come from can be, must have the two syllables marked by the brace '⏟' (distinct from the slur marking elision) in one position:

(22a) The long brook falling thro' the cloven ravine
w s w s w s w s

(‘Oenone,’ 8)

(22b) In cataract after cataract to the sea
w s w s w s w s w s

(*ibid.*, 9)

As Kiparsky (1977) observed, building on Young (1928), whenever such sequences involve stress, they consist precisely of a short stressed vowel followed by a single consonant (or a pair that can be parsed together as an onset) and then another unstressed vowel all in the same word, as in (22b), or the additional examples with different vowels in (23):

(23a) Ineffable beauty, out of whom, at a glance
w s w s <> w s w s w s

(‘Tiresias,’54)

(23b) To some great citizen, win all praise from all
w s w s w s w s w s

(*ibid.*, 82)

(23c) Here trampled by the populace underfoot
w s w s w s w s w s

(*ibid.*, 166)

Because they involve stressed syllables in polysyllabic words that cannot be understood as somehow potentially reduced to monosyllables, these sequences occur only in strong positions (unless initial). They thus resemble the structures of 'resolution' found in classical and in Old English meters, in which a single position is realized by a sequence of this type. In fact, those structures have been argued to play a role in ordinary stress systems, as a particular variant of the phonological foot type called 'moraic trochees,' normally consisting of two light syllables with stress on the first (Hanson, 1992; Hanson and Kiparsky, 1996). English iambic meters that allow resolution have thus been proposed to actually not be syllabic at all; instead of requiring a single syllable in each position, they require a maximum of a single moraic trochee of this type in each position (Hanson and Kiparsky, 1996). Because that is a unit of stress assignment, the presence of pairs of syllables with no stress on either follows – as in (22a) – and indeed is virtually always found wherever resolution is (incidentally giving each line in (22b) and (23) an alternative scansion). Thus, there are really two distinct types of iambic meter in English: one is based on having a syllable in each position, and one measured by this other principle. As Halle and Keyser (1999) observed (although analyzing the phenomenon rather differently) the distinction was recognized by Robert Frost, who called the two 'strict' and 'loose' iambics.

Stress in 'Strong-Stress' Meters

What is shared by the two versions of iambic meter just discussed is their constraint against having the stressed syllables of polysyllabic words in weak positions, as well as their iambic template. That is not, however, the only constraint on stress that English meter can have, even in meters sharing that template.

Most strikingly, the variable syllable count illustrated in (22) and (23) occurs in the exact same form not only in the loose iambic meter illustrated there, but also in another meter, sometimes called 'iambic-anapestic' (Leino, 1986), illustrated in (24) by lines from Tennyson's hexameter poem 'The Voyage of Maeldune.' In this meter, there is no constraint against stress in weak positions, so resolution can occur in there as in *melon* and *flourished* in (24b and 24c). Instead, there is a requirement that the strong positions must contain stress:

(24a) And the fig ran up from the beach and rioted over the land
w s w s w s w s w s w s
('The Voyage of Maeldune',58)

(24b) And the warm melon lay like a little sun on the tawny sand,
w s w s w s w s w s w s
(*ibid.*, 57)

(24c) And the poplar and cypress unshaken by storm flourished
w s w s w s w s w
up beyond sight
s w s
(*ibid.*, 15)

This requirement of stress in strong positions aligns this meter with the classical dactylic hexameter, to which it clearly makes reference with its six-foot line, which in addition to the variation between one and two syllables in weak positions discussed above has a requirement of heavy syllables in strong positions. It also aligns it with Old English meter, which differs in having a tetrameter template (Getty, 1998), but likewise in addition to its variation in syllable count has a requirement of stress in strong positions. This meter is also the basis of Hopkins' 'sprung rhythm' (Kiparsky, 1989; Hanson, 1992).

This iambic-anapestic meter is in its turn distinct from genuine anapestic meter, which shares this property of requiring stress in strong positions, but does not does not have variable syllable count (Hanson, 1992). Rather, it has a regular triple rhythm (apart from variations attributable to catalexis, extrametricality, elision, and diaeresis, which are in principle available to all meters). This can be understood as deriving from a different template genuinely comprising three positions, though perhaps, as Prince (1989) suggested, built hierarchically out of groups of two as in (25), in keeping with hypotheses that only binary structures figure in the phonology of linguistic rhythm, and involving a natural differentiation in stress between the first and second positions of the subdivided weak position, as indicated. Only the unsubordinated strong position requires stress, and the subordinated weak position eschews stressed syllables of polysyllabic words as in iambic meter:

(25)

This meter is illustrated in (26) by lines from some anapests Tennyson wrote as a youngster, pairs of tetrameters that join to form octometers:

(26) For its sweet breathing tones in forgetfulness languish,
s w s s w s s w s s w s <>
And around it the ivy shall weave a green veil.
s w s s w s s w s s w s
('Written by an Exile of Bassorah')

Alignment

Finally, although they do not figure conspicuously in English metrical descriptions, this survey of principal elements of meter would be incomplete without mention of correspondence rules that regulate neither syllable count nor stress, but the **position** of linguistic boundaries, like those of words, phrases, or sentences, in relation to the boundaries in the template, such as those of feet, cola, or lines. Such rules are central to the canonical meters of some languages; in the classical French *décasyllabe*, for example – a meter that shares exactly the same template and rule for syllable count as the strict English iambic pentameter, and likewise used for sonnets – there must be a word boundary (a caesura) between the syllables in the fourth and fifth positions, which is to say between the cola of the structure in (5a), as in (27a); a line like Tennyson's in (27b) would be unmetrical:

(27a) Mais ce repos, qui soulage le monde
w s w s w s w s w s <>
(du Bellay, 'l'Olive')

(27b) It little profits that an idle king
w s w s w s w s w s
('Ulysses,' 1)

Such rules also find an analogue in language, in, for example, constraints mandating coincidence of prosodic boundaries with those of other linguistic constituents (McCarthy and Prince, 1993). And even though rules of this kind have received comparatively little attention in English metrics, and indeed do not figure as centrally there as the other rules discussed do, they are not without a role in English: they underlie constraints on enjambment (Hayes, 1989); they appear as statistically significant tendencies in some poets' practice (Duffell, 2002); they govern subregularities of well-formedness noted by Kiparsky (1977); and they exert enormous aesthetic influence

(Kiparsky, 1977). This last was already noted above in connection with the alternative metrical analyses of 'Home They Brought Her Warrior Dead' in (19), but it can also be seen here that the opening line of 'Ulysses' in (27b), for example, in not allowing the rest that comes from having a word boundary coincide with a foot boundary until the end of the line, where any such restfulness is undone by enjambment, portrays Ulysses' restlessness at being consigned to spend the remainder of his life ruling over the unstriving Ithacans characterized metrically in just the opposite way:

(28) That hoard, and sleep, and feed, and know not me

('Ulysses,' 5)

Conclusion

The foregoing has of course only scratched the surface of the analysis of some properties of some of the most familiar meters of one language. However, even in this brief survey it can be seen that at every turn, the question of why meters have the precise properties they do seems to be illuminated by considering those properties not as accidental conventions, but as manifestations of the fundamental nature of meter as a linguistic form. In turn, simply understanding what those properties are allows a richer appreciation of how poets have used meter to create aesthetic effects.

Understanding these properties has also allowed the broaching of new questions about meter, such as how to model intuitions about not just well-formedness, but also complexity (Friedberg, 2002), the organization of lines into stanzas (Hayes and MacEachern, 1998; Kiparsky, forthcoming), or the principles governing how texts are set to music (Hayes and MacEachern, 1998; Kiparsky, forthcoming). Understanding these properties is also a significant preliminary to questions – made especially compelling by 20th-century poetic practice – of how meter differs from the organizing principles of compositions that are exceptionally rhythmic yet not metrical (Hartman, 1981), and even how meter differs from music itself. Further study of meter in more challenging English forms and in other languages is thus a wide open and rewarding field of research in linguistics, literature, and aesthetics today.

Metonymy: History and Terminology

Metonymy has been studied for at least 2000 years by rhetoricians, for 200 years by historical semanticists, and for about two decades by cognitive linguists. More recently, metonymy has come to be recognized as a fundamental cognitive and linguistic phenomenon alongside metaphor that manifests itself in the lexicon as well as in grammar (Panther and Radden, 1999; Barcelona, 2000; Nerlich and Clarke, 2001; Dirven and Pörings, 2002; Panther and Thornburg, 2003; Steen, 2004).

The earliest definition of metonymy can be found in the *Rhetorica ad Herennium*, written before 82 A.D.:

> *Denominatio* est, quae ab *rebus propinquis et finitimis* trahit orationem, qua possit intellegi res, quae non suo vocabula sit appellata.
>
> *Denominatio* [i.e., 'metonymy'] is a trope that takes its expression from *near and close things* and by which we can comprehend a thing that is not denominated by its proper word. (Koch, 1999: 140–141)

Metonymy: History and Terminology

Metonymy has been studied for at least 2000 years by rhetoricians, for 200 years by historical semanticists, and for about two decades by cognitive linguists. More recently, metonymy has come to be recognized as a fundamental cognitive and linguistic phenomenon alongside metaphor that manifests itself in the lexicon as well as in grammar (Panther and Radden, 1999; Barcelona, 2000; Nerlich and Clarke, 2001; Dirven and Pörings, 2002; Panther and Thornburg, 2003; Steen, 2004).

The earliest definition of metonymy can be found in the *Rhetorica ad Herennium*, written before 82 A.D.:

> *Denominatio* est, quae ab *rebus propinquis et finitimis* trahit orationem, qua possit intellegi res, quae non suo vocabula sit appellata.
>
> *Denominatio* [i.e., 'metonymy'] is a trope that takes its expression from *near and close things* and by which we can comprehend a thing that is not denominated by its proper word. (Koch, 1999: 140–141)

A classic example of the rhetorical use of metonymy is 'The pen is mighter than the sword.' In 1980 the cognitive linguists Lakoff and Johnson (1980) introduced the concept of conventional or conceptual metonymy alongside the concept of conceptual metaphor. They argued that metaphor and metonymy are not just rhetorical devices, but pervade our talking, thinking and acting in the world. According to this new view, a conventional metonymy is a metonymy that is commonly used in everyday language in a culture to give structure to some portion of that culture's conceptual system. Metonymies can be based on many cognitive and culturally based conceptual relationships. To give only two examples (there are more later in this article): in 'Napoleon lost at Waterloo,' metonymy is based on the controller-controlled relationship; in 'The kettle is boiling,' metonymy is based on the container-contents relationship. One of the more recent definitions of metonymy, rooted in this new view of metaphor and metonymy, is the following:

> Metonymy is a cognitive process in which one conceptual entity, the vehicle, provides mental access to another conceptual entity, the target, within the same idealized cognitive model. (Radden and Kövecses, 1999: 21)

Here the 'near and close things' referred to in the *Rhetorica ad herennium* have been replaced by Lakoff's 'idealized cognitive models.' Other researchers work with the terminology of domains, schemas, or frames instead.

In between the *Rhetorica ad herennium* and the more recent publications, research into metonymy picked up ideas from traditional rhetoric (metonymy was part of the tropical triad of metaphor, metonymy, and synecdoche or else of the quadruple of metaphor, metonymy, synecdoche, and irony), from associationist psychology (it inherited the distinction between contiguity and similarity as defining the difference between metonymy and metaphor), from Saussurian linguistics (it inherited the distinction between syntagmatic and paradigmatic relations, which Jakobson (1956) used to distinguish between metaphor and metonymy), from interactionist approaches to metaphor (Black, 1979) (it inherited the distinction between tenor and vehicle), and from Gestalt psychology (it inherited the distinction between figure and ground). This last influence has come to the fore in recent years through Langacker's work and has been successfully integrated into various frame-based analyses of metonymy.

An example of this type of analysis can be found in Panther and Radden (1999). They study the following metonym:

> (1) The first violin has the flu.
>
> The concept 'the first violin' is part of a knowledge structure that it evokes. As a musical instrument, a violin is immediately associated with the violinist as the player of that instrument. Moreover, the first violinist is defined as a member of a larger group of musicians, the symphony orchestra. Among the musicians of the orchestra, the first violinist is the most outstanding member. Finally, our knowledge of orchestras includes, among other things, the notion of music and its representation in scores. The predication *has the flu* as well as the attribute *first* trigger a non-literal interpretation of the noun phrase *the first violin*. Thus, the metonymic reading in [1] involves a shift from the instrument to the musician as the most readily available element in the frame. Through this metonymic shift, the reference point ('the first violin') is backgrounded and the desired target ('the first violinist') is foregrounded. (Panther and Radden, 1999: 9)

This analysis draws on Langacker's (cognitive) distinction between reference-point and target (1993: 3). For Langacker, metonymy is a reference-point phenomenon in that "the entity that is normally designated by a metonymic expression serves as a reference point affording mental access to the desired target, i.e. the entity actually being referred to" (Langacker, 1987: 385–386).

The distinction between reference-point and target can be compared to those made in pragmatics between what is said and what is meant, what is said and what is referred to, what is said and what is only implied, and between the conventional meaning/referent and the intended meaning/referent of the words used. This brings us to the question: Is metonymy a conceptual/cognitive or a referential/pragmatic phenomenon? Or both?

Metonymy: From Cognition to Social Interaction

At present, there are two camps in the cognitive linguistic community: those who see metonymy essentially as a referential and/or pragmatic phenomenon and those who see it essentially as a conceptual and cognitive one (Nunberg, 1978; Feyaerts, 1997: 74–76). For Seto, for example, metonymy "is a referential transfer phenomenon based on the spatio-temporal contiguity as conceived by the speaker between an entity and another in the (real) world" (Seto, 1999: 91). At the other end of the spectrum we find Kövesces and Radden's (1998) work, in which metonymy is radically defined as a conceptual phenomenon. Lakoff and Turner (1989: 103) were rather more cautious when they wrote that metonymy "is used primarily for reference: via metonymy, one can

refer to one entity in a schema by referring to another entity in the same schema."

More recently, Warren has made the distinction between referential metonymy and propositional metonymy, in which the former is based on reference-based relations, such as between cause and effect or container and content, the latter on antecedent-consequent relations (or if-then relations). An example of referential metonymy is: "*The bathtub* is running over. [That which is in the tub, i.e., the *water*]" (Warren, 1999: 127). An example of propositional metonymy is: "It won't happen while I still *breathe*. [If he breathes, then he lives]" (p. 129). Warren defines referential metonymy in the following way:

> For anything to qualify as a referential metonym, the following applies:
> (i) it should have a referent,
> (ii) the intended referent is not explicitly mentioned but its retrieval depends on inference,
> (iii) inference is made possible because there is some connection between the mentioned referent (the trigger) and the implied referent (the target) deemed so well known that in the context in question the former will automatically suggest the latter. (Warren, 1999: 123)

For Warren, "the actual meaning-construction of metonyms depends on successful referent-identification. We cannot be certain that we have worked out the correct metonymic extension, unless we believe we know what the referent is" (Warren, 1992: 68). It seems that our ability to create and understand metonyms is grounded in our ability to infer the referential intentions of others in linguistic interaction (see Burling, 1999).

Metaphor and Metonymy

From this point of view, one can argue that metonymy is a pragmatic strategy used by speakers to convey to hearers something new about something already well known. This distinguishes it from metaphor, which can be regarded as a pragmatic strategy used by speakers to convey to hearers something new that cannot easily be said or understood otherwise or to give an old concept a novel, witty, or amusing package. Using metaphors, speakers tell you more than what they actually say; using metonyms they tell you more while saying less. From the point of view of the hearer, metaphor is a strategy used to extract new information from old words, whereas metonymy is a strategy used to extract more information from fewer words. Metaphor is a conceptual and semantic simulation device, whereas metonymy is a conceptual and syntactic abbreviation device. Both are pragmatically grounded and exploit cognitive mapping processes.

An example of the use of a metaphoric strategy would be the child who points to an oil spill on the road and says:

(14) "Look: A dead rainbow!" (Todd and Clarke, 1999)

An example of the use of a metonymic strategy would be the German passenger who, in 1997, looked down from a plane approaching Heathrow and said to his wife, when pointing to a cow:

(15) "Look: BSE!"

In the first case, the mother has to *create* a relation between the oil spill shimmering in many colours and a rainbow, a rainbow that seems to have been reduced to a sad puddle. In the second case the wife can *exploit* a given relation between cows and the potentially deadly disease they might carry. Here the relation is not created but presupposed (Bredin, 1984: 57). In the case of metonymy, the hearer has to find the target item and interpret it by retrieving a relation between it and the trigger. As conceptual metonymic relations (such as cause-effect, part-whole, container-content) are cognitively well entrenched, the interpretation of metonymy is less demanding than the interpretation of a metaphor, where the possible links between what is said and what is meant are relatively open-ended (Warren, 1992: 99).

Whereas our ability to leap through mental spaces and establish unexpected but enlightening links between features of these spaces underlies metaphor, our ability to access an entire state, situation or object from the mention of some part is the hallmark of metonymic thinking (Warren, 1999: 122).

Both metaphor and metonymy can lead to semantic change and polysemy. In the case of metonymic sense extension, the pathways we use seem to be cognitively entrenched and rooted in patterns of human action and experiences of handling objects. Many linguists have tried to establish typologies of these 'pathways' of metonymic sense extension (Nerlich *et al.*, 1999), but one example will suffice here. In 1981, Norrick distinguished the following types of metonymy and correlated them with 18 metonymic principles. This typology includes the part-whole relationship often called synecdoche (on the metonymy and synecdoche, see Nerlich and Clarke, 1999; Seto, 1999, 2003).

I. Cause – effect
   1. Cause – effect
   2. Producer – product
   3. Natural source – natural product
   4. Instrument – product

II. Acts and major participants
   1. Object – act
   2. Instrument – act
   3. Agent – act
   4. Agent – instrument

III. Part – whole
   1. Part – whole
   2. Act – complex act
   3. Central factor – institution

IV. Container – content
   1. Container – content
   2. Locality – occupant
   3. Costume – wearer

V. Experience – convention
   1. Experience – convention
   2. Manifestation – definition

VI. Possessor – possession
   1. Possessor – possession
   2. Office holder – office

This use of well-established conceptual pathways makes metonymy quite different from metaphor.

As a result of the use of a metaphor, salient features of words and objects are blended across semantic and conceptual space. Metaphor binds distant conceptual domains together and creates conceptual networks. As a result of the use of a metonym, a word absorbs salient features inside a referential or conceptual space or, to put it differently, it spreads out over conceptual space(s). Whereas metaphor creates new meaning and possibly new conceptual structures, metonymy incorporates free-floating meaning, steals meaning from related concepts and conceptual domains, and thereby changes or strengthens given conceptual structures.

Synchronically, metonymies are created by exploiting contiguous relations inside a conceptual/referential domain. This can have a rhetorical effect, as in "Look, BSE!" or else be the result of pragmatic constraints on cost-effective communication (as in 'The appendix has just passed out'). Diachronically, metonymies can spread serially (which can lead to synchronic polysemies, such as *panel* which can mean either 'flat distinct section of a larger surface, such as that in a door' or 'a group of people as a team' or 'list of jurors,' etc., similar to *board*) from, say, *board* to table to food (as in *bed and board*) to the people who set around the table, etc. This chaining follows 'natural' relations, quite often based on immediate proximity between objects and people in space. As interlocutors do not cross distant conceptual boundaries, they tend not to exploit and create the wide conceptual networks on which metaphorical expressions are based.

Conclusion

The definition of metonymy inside cognitive linguistics is still fluid and this article could only provide a glimpse into some aspects of research. It did not deal with metonymy and salience (Paradis, 2004), metonymy and qualia, the interaction between metaphor and metonymy, and the universality of conceptual metonymies (see Panther and Thurnburg, 2003).

Metrical Phonology

C B McCully, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Metrical phonology is a cover term applied to explorations of stress and rhythmical phenomena. Although metrical phonology yielded important insights into the representation and description of metrical verse in English and other languages (Hayes, 1984, 1989; Kiparsky and Youmans, 1989; Russom, 1987, 1998), nevertheless the impression of metrical phonology was most clearly felt in the analysis of syllable structure, word stress, and phrasal rhythm. In these fields, research on the nature and construction of nonlinear representations became intense after the publication of Liberman and Prince's seminal 1977 article. Important early contributions to the analysis of word and phrase stress were made by Hayes (1982), Giegerich (1983, 1985), Prince (1983), and Selkirk (1984). Metrical phonology then gained further impetus from the publication of Halle and Vergnaud (1990), a strand of research that developed into the 1990s and saw publication of revised, or entirely new, kinds of representational

Although metrical phonology yielded important insights into the representation and description of metrical verse in English and other languages (Hayes, 1984, 1989; Kiparsky and Youmans, 1989; Russom, 1987, 1998), nevertheless the impression of metrical phonology was most clearly felt in the analysis of syllable structure, word stress, and phrasal rhythm. In these fields, research on the nature and construction of nonlinear representations became intense after the publication of Liberman and Prince's seminal 1977 article. Important early contributions to the analysis of word and phrase stress were made by Hayes (1982), Giegerich (1983, 1985), Prince (1983), and Selkirk (1984). Metrical phonology then gained further impetus from the publication of Halle and Vergnaud (1990), a strand of research that developed into the 1990s and saw publication of revised, or entirely new, kinds of representational

models (Halle and Idsardi, 1995). The mid-1990s also saw publication of what is perhaps still the most significant single work of summary and analysis of the nonlinear project. This was Hayes (1995). At the same time, nonlinear representational models helped explore topics in diachronic linguistics, particularly with respect to the history of English stress (McCully and Hogg, 1990; Lass, 1992; Lahiri *et al.*, 1999), and this strand of research also informed analyses of some of the same phenomena, as these were developed in a variety of optimality-theoretic approaches (Pater, 1995; Minkova, 1997; Gasiorowski, 1998). Metrical phonology also made its impression on the foundation of optimality theory (OT; Prince and Smolensky, 1993), and elements of its particular kinds of nonlinear representation can be discerned in important modifications of OT (McCarthy and Prince, 1993).

Trees and Grids

From the beginning, metrical phonology was relational in character. That is, stress was not viewed as an absolute property of syllables and words. Rather, syllables and words were analyzed as either stronger than, or weaker than, adjacent syllables or words. Stress was not seen, as in Chomsky and Halle (1968), as a matter of *degree*, with specifiable phonetic correlates; it was a matter of relative prominence. Therefore, a word of two syllables, with most prominent stress on its initial syllable, might be notated as follows, where *S* stands for 'stronger than' and *W* for 'weaker than':

(1)

S and *W* can never exist in isolation, nor can *S* be sister to *S*, or *W* a sister to *W*. Additionally, and therefore, ternary relationships are debarred. The representations found in (2) are ill formed:

(2)

Notice that, a notation such as [W S] would in principle be well formed for both the following English examples:

(3)

Clearly, there are differences in the prominence of the syllables *de-* in *delayed, an-* in *antique*. One difference is phonetic (*an*-is rarely or ever subject to reduction to schwa, cf. */œnti:k/), whereas the vowel shape in the first syllable of *delayed* will always display relative stresslessness. Consider also the strings *delayed flight* and *antique spoon*. In the first, the prominence pattern of *delayed* is unaltered. In the second, prominence on *antique* shifts to [S W]. Trees of the kind sketched in (3) have no way of capturing the distinction in prominence patterns of words such as *delayed* and *antique* (both are underlyingly – one might say – [W S]), and such tree representations cannot, in themselves, predict prominence switching.

To remedy this problem, the earliest version of metrical phonology used a supplementary notational device, the metrical grid. Grids were built from the bottom upward, and no gaps in construction were allowed. Further, grids, unlike trees, could 'read' which syllables were stressless, or nonreducible and therefore 'footed,' along with which syllable within the phrase was most prominent. Consider the representations in (4):

(4a)	de	layed	flight	
	x	x	x	Level 1
		x	x	Level 2
			x	Level 3
(4b)	an	tique	spoon	
	x	x	x	Level 1
	x	x	x	Level 2
		x	x	Level 3
			x	Level 4

In (4a), syllables are grid marked at Level 1, then prominence relations are projected onto the grid at Levels 2 and 3. Once this has been achieved, then the phrase-final word in both examples must receive more grid marks than anything else in the string, because both *flight* and *spoon* are (and will remain) the heads of their respective phrases: they are the strongest elements of each string. Compare grid structures in (4a–b) with their associated trees (5a–b). Notice how the strongest word of each phrase is uniquely dominated by *S*:

(5a)

(5b)

Tree structures expressed prominence relations, but were not in themselves structured enough to capture nonrelational facts (such as the degree of prominence accorded to *an-* in *antique*, compared with *de-* of *delayed*). To express those nonrelational facts, the grid was needed. Trees might express the environments for, i.e., the 'permission,' for rhythmically motivated change, but grids expressed the 'pressure' for such change, largely because certain configurations of grid marks could be defined as clashing or lapsing.

Clashes and lapses can be defined as follows. A grid *clash* occurs when grid marks in two directly adjacent columns have marks on two contiguous rows (not counting Level 1). A grid *lapse* occurs when grid marks in two directly adjacent columns have equal marking on the same row. Thus, the grid found in (6a) expresses a clash, that in (6b), a lapse:

(6a) Grid clash

Level 1	x	x	x
Level 2	x	**x**	**x**
Level 3		**x**	**x**
Level 4			x

(Grid clash at Level 3)

(6b) Grid lapse

Level 1	x	x	x	x
Level 2		**x**	**x**	x
Level 3				x
Level 4				

(Grid lapse at Level 2)

Repairs take place so that the new grids are 'better' (in a sense to be shortly defined here) than their underliers. In (6a), for example, a possible repair strategy would be to *move* the clashing grid mark at Level 3 leftward from the site of the clash, relocating it atop the next adjacent leftward column. In (6b), a possible repair strategy might be to *add* a grid mark to column 2, Level 3, simultaneously (and consequentially) adding a further mark to column 4, Level 4, so that that column remains strongest of the string:

(7a) Grid clash, repaired

Level 1	x	x	x
Level 2	x	x	x
Level 3	**x**		x
Level 4			x

(7b) Grid lapse, repaired

Level 1	x	x	x	x
Level 2		x	x	x
Level 3		**x**		x
Level 4				**x**

Repaired grids in (7a–b) may be said to be 'better' because they not only express alternating structures, but also eurhythmic ones, in the sense of Hayes (1984). Alternation may be defined as follows: where grid marks are adjacent on one level, but where the adjacent marks are separated at the next lower level by one (and only one) grid mark. Consider here the structures expressed at Level 3 in (7a–b). In both instances there are adjacent grid marks in the first and third columns. But at the next level down, Level 2, the erstwhile adjacent columns and their markings are separated by an intervening grid mark (the boxed mark in (8a–b) below):

(8a) Grid clash, repaired

Level 1	x	x	x
Level 2	x	$\boxed{x}$	x
Level 3	x		x
Level 4			x

(8b) Grid lapse, repaired

Level 1	x	x	x	x
Level 2	x	$\boxed{x}$	x	
Level 3	x		x	
Level 4			x	

In Hayes (1984), disyllabic outputs were only one facet of the rhythmical phenomenon of eurhythmy, where quadrisyllabic intervals (for example) could also be optimally well formed provided that alternation was defined on every relevant lower level of the grid:

(9) Quadrisyllabic intervals and eurhythmic structures

Level 1	x	x	x	x	x
Level 2	x		x	x	x
Level 3	x		x	$\boxed{x}$	x
Level 4	x		$\boxed{x}$		x
Level 5	x				x
Level 6					x

The marks at Level 5 – spaced four syllables apart – are adjacent, but separated evenly at the next lower level (the boxed mark at Level 4). Again, the marks in columns 3 and 5 of Level 4 – spaced two syllables apart – are adjacent, but are separated evenly at the next lower level (the boxed mark at Level 3). The grid seen in (9) is perfect: no addition or movement of grid marks is possible, and none would be motivated. In addition, the structure obeys two principles of eurhythmy, the disyllabic principle (Hayes, 1984: 48), and the quadrisyllabic principle (Hayes, 1984: 46).

It would be possible to express some of these pressures and permissions in annotated tree structures, and encode rhythmicity into rewrite rules, as in (10):

(10a) Tree-only rhythmicity (I)

Condition: 1 is not a stressless syllable

(10b) Tree-only rhythmicity (II)

Condition: 1, 2 may dominate lexical monosyllables

Such representations and rules were explored in papers and other work by Giegerich (1980, 1983, 1984, 1985). This approach eschewed grids, and sought to develop a truly relational approach to the representation of word and phrase stress. The most innovative feature of this work lay in the representation of lexical monosyllables in English. In grid-only formats (and with the exception of the grid-only representations developed in Selkirk, 1984), the representation of lexical monosyllables tended to be a matter of stipulation. Such items were inherently stressed (because they were lexical items, word stress had clearly applied to them somewhere and somehow), and therefore, they were in some sense 'strong,' or perhaps 'footed.' In versions of Giegerich's early work, lexical monosyllables could not properly be S(trong) *unless that S had a sister W*. It followed that a lexical monosyllable, in a citation form, might be followed by a *W* node that dominated a zero syllable. Compare the representations of the numeral *three* below. In (11a), *three* is given a grid representation, a somewhat stipulative height capturing the fact that it is a syllable, a foot, and a (prosodic) word. In (11b), the syllable is represented as being dominated by terminal *S*, with accompanying *W* zero syllable:

(11a) x (Level 3, 'word level')
x (Level 2, 'foot level')
x (Level 1, 'syllable level')
three

(11b)

The role of zero syllables in the rhythmic and junctural phenomena of English (and other languages) has never been explored as fully, perhaps, as it deserves, though see also Burzio (1994) for a different account. Allowing zero syllables into a theory of representation also had a consequence: some zeros would have to be post cyclically deleted, making derivations cumbersome (on defooting, see Giegerich, 1983: 8–17). What might be called 'mainstream' nonlinear phonology preferred, as the 1980s progressed, to explore the representation of stress and rhythm as these might be captured in grid-only representations. There were exceptions – the continuing work of Giegerich, and the representational program fronted by Halle (Halle and Vergnaud, 1990; Halle and Idsardi, 1995) – but grid phonology, as it had been developed by Prince (1983), Selkirk (1984), and Hayes (1984), seemed so exciting, so fresh, and so economical that it was among the columns and levels of the metrical grid that perhaps the most significant advances in nonlinear theory took place.

Stress and Extrametricality

Many of these advances concern word stress. It had been well known ever since Chomsky and Halle (1968) that word stress could be seen as operating under a set of principles that were both *directional* and *iterative*. But Hayes (1982) postulated that certain constituents lying at the edges of stress-assignment domains might be *extrametrical* to stress-assignment processes. Consonant segments, syllables, affixes of certain kinds, or even whole words might, in principle, be extrametrical. A particularly interesting (because complex) example of the working of extrametricality comes in the presumed stress behaviour of English nouns, where (i) word-final *consonants* are marked as extrametrical, and (ii) word-final *syllables* are listed as extrametrical (except in the case of some exceptionally behaving loan words, which are listed as *not* undergoing default extrametricality rules). A noun such as *torment*, for example, stressed on its initial syllable, would have the following lexical entry prior to the operation of any stress parsing:

(12a) torment‡ (final C extrametrical by Consonant Extrametricality)
(12b) torment‡ (final syllabic Rhyme extrametrical by Noun Extrameticality)

Because Consonant Extrametricality is extrinsically ordered before Noun Extrametricality, a noun such as *agenda* would have the following lexical entry prior to stress parsing:

(13a) agend~~a~~ (Consonant Extrametricality applies vacuously)
(13b) agenda (final syllabic Rhyme extrametrical by Noun Extrametricality)

If *torment* and *agenda* are then subject to a right-to-left parse, the syllables available to be scanned are the first syllable of *torment*, and the medial syllable of *agenda*. In the (tree-based) version of stress rules given in Hayes (1982), these syllables are footed. In the case of *torment*, and because no other stress rules can apply, the extrametrical final syllable is incorporated into the output structure by a postcyclical process of Stray Syllable Adjunction, see (14a–b), where Σ stands for 'foot'

(14a)

(14b)

In *agenda*, though, once the medial syllable has been parsed the stress-assignment rule must continue to parse leftward, where it reaches the syllable *a-*. This is footed underlyingly, though will have its honorary foot status postcyclically adjusted (i.e., it will be subject to 'Defooting'). The two feet created by the basic stress assignment process are then relationally labeled, in this case [W S] (the 'Word Rule'). And in a final adjustment, the initial foot is stripped, and in its new guise as a 'mere' W syllable, is adjoined to an immediately preceding/following foot – in this instance, a following foot. The stages of stressing can be seen in (15a–c):

(15a)

(15b)

(15c)

This tree-based, rule-based approach, for all its conceptual neatness, seems also somewhat inelegant, particularly in the need for (postcyclic) destressing rules. It was not long before modified grid-based representations were developed, partly owing to the pioneering work of Selkirk (1984), who developed a theory of word stress and juncture whereby

- Representations were wholly grid based
- Extrametricality applied prior to stress assignment
- Rhythmicity was 'written into' word-stress assignment, in that the addition of grid marks (Beat Addition) was motivated by the Principle of Rhythmical Alternation at each level of a derivation
- The need for constituency – particularly, for the constituent 'foot' – was driven by the grid alignment of the sentence, rather than by inherent properties of the (presumed) foot, and therefore the new representations apparently could *dispense* with constituents such as 'prosodic foot' and 'prosodic word.'

In the spirit of Selkirk (1984), (16a–c) shows the scansion of the English (loan) word *chimpanzee*. In (16a), syllables are aligned one-to-one with grid marks (Demibeat Alignment, DA). In (16b), heavy syllables receive grid marks at the second level of the grid (Heavy Beat Rule, HBR), along with initial syllables (Initial Beat Rule, IBR). And in (16c), main word stress is projected onto the rightmost grid column by the Main Stress Rule (MSR):

```
(16a)              (16b)              (16c)
                   x   x   x                  x
                                      x   x   x
x   x   x          x   x   x          x   x   x
chimpanzee         chimpanzee         chimpanzee
```

Because rhythmicity applies throughout a derivation, grid (16c), which contains a grid lapse, is subject to Beat Addition:

```
(16d) x
      x   x
      x   x   x
      x   x   x
      chimpanzee
```

Given the phonetic evidence for the phonological foot, however, such parsimonious derivations were arrived at prematurely. In this model, constituency can be *inferred* (if one wishes so to infer) from particular grid arrays, but constituency is not *defined* in the representations.

Stress and Parameters

A new strand of metrical phonology attempted to address this question and to some extent underlies the representations found in Hayes (1995). This was the

approach developed in Halle and Vergnaud (1990), a modification of which can be found in Halle and Idsardi (1995). In these models, stress assignment was

- Cyclic
- Directional
- Constituentized
- Parametrized.

Consider parameters (and see also Hayes, 1995: 54–55, from which some of the following is drawn). The edge of the word from which stress parsing begins is a parameter, and so in theory it would be possible for languages to have a right-parameter set (thus present-day English or Latin), or a left-parameter set (thus Hungarian). A further parameter might be the choice of foot type (are feet maximally unary? binary? unbounded?). Another might be constituent labeling (initial, as opposed to final, prominence). Another might be iterativity (whether stress assignment rules apply once only, or iterate across domains).

Now consider a specimen representation from the 'parametrized grids' found in Hayes (1995). In (17a) the relevant parameters are set out. In (17b) the result of the parameters is given (the 'application of the stress rules'):

(17a) Hungarian stress, parameter settings (Hayes, 1995: 54–55)
- i Feet are maximally binary.
- ii Heavy syllables may occur in weak position.
- iii Feet have initial prominence.
- iv The head of a foot need not be a heavy syllable.
- v Parsing is left to right.
- vi Foot construction is iterative.
- vii Foot construction is allowed to create a new layer of structure.

(17b) Hungarian stress, word of 8 syllables

(σ = syllable; 'x' represents a stressed syllable, '.' an unstressed syllable, and '()' the boundaries of the foot)

```
(x .)   (x .)   (x .)   (x .)
σ σ     σ σ     σ σ     σ σ
→ direction of parse
```

Halle and Idsardi's (1995) approach incorporates similar features, but is an even more parsimonious version of parametric theory in that it dispenses with superfluous constituent brackets. Headedness can be read off any grid if the relevant element is directly adjacent to a left/right bracket, and once headedness – or potential headedness – has been identified, it is a simple matter to *project the head of the constituent* by adding a grid mark at the next higher level. Thus, Halle and Idsardi's (1995) approach may be called the 'parameters and projections' approach to stress. Certain kinds of syllable have a boundary *projected* into Level 0 of the grid. Then the left-/rightmost element of each constituent is *projected* onto the next line of the grid (Level 1). Then, to mark the edge of the string, a further boundary is projected – and here, parameters can be set to project a *left boundary* to the *left* of the *leftmost* element of the grid, or alternatively, a *right boundary* to the right of the rightmost, or a *right boundary* to the *left* of the rightmost . . . and so on.

A specimen representation – which happens to be part of the stress representation of Koya (Halle and Idsardi, 1995: 409) – can be found in (18):

(18) Parameters and projections in Koya (CV = light syllable, CVX = heavy syllable)

```
 x   x   x   x     x   x   x     x   x   Level 0
CV  CV  CV  CVX   CV  CV  CVX   CV  CV
```
(Longhand: 'Project each syllable head into a representation at Level 1')

```
 x   x   x   (x    x   x   (x    x   x   Level 0
CV  CV  CV  CVX   CV  CV  CVX   CV  CV
```
(Longhand: 'Project the left boundary of heavy syllables onto Level 0.')

```
                x               x           Level 1
 x   x   x   (x    x   x   (x    x   x   Level 0
CV  CV  CV  CVX   CV  CV  CVX   CV  CV
```
(Longhand: 'Project the leftmost element of each constituent onto the next level of the grid.')

```
 x               x               x           Level 1
(x   x   x   (x    x   x   (x    x   x   Level 0
CV  CV  CV  CVX   CV  CV  CVX   CV  CV
```
(Longhand: 'Mark an edge. Place a left boundary to the left of the leftmost constituent, and project its head onto the next grid Level.')

```
 x                                           Level 2
(x               x               x           Level 1
(x   x   x   (x    x   x   (x    x   x   Level 0
CV  CV  CV  CVX   CV  CV  CVX   CV  CV
```
(Longhand: 'Project main stress. Apply Edge Marking – left/left/left – and project the head of the created constituent onto the next level of the grid.')

Conclusion

As the millennium turned, those working with non-linear representations continued – some still continue – to ask questions about which, and how many, parameters, apply to a given language; questions concerning the extent of an inventory of foot types still prove troublesome (particularly that concerning the existence of a possible 'Germanic foot,' see here Dresher and Lahiri, 1991; Lahiri *et al.*, 1999); some issues concerning the nature and representation of word-stress remain contentious (McCully, 2002); and many questions concerning the application of metrical phonology to both diachrony and metrics remain open, unsatisfactorily answered (McCully, 1997), or badly put. As scholarly attention has tended to move from the representation of word and phrase

stress to an ever closer examination of the phonology/morphology interface, as this might be captured in a variety of OT models, then 'metrical phonology' has seemed to become an unfulfilled project – despite still having a great deal to say.

This article is reproduced from the previous edition, volume 5, p. 2485, © 1994, Elsevier Ltd.

The national language of Mexico and the mother tongue of over 90% of its 84 million inhabitants (1989) is Spanish, making Mexico the largest Spanish-speaking country in the world. In addition, there are well over 50 indigenous minority ethnolinguistic groups, amounting to a total of over 6 million people. Many of these groups subsume more than one language.

Most of the surviving indigenous languages are in the eastern half of the country, mainly in rural areas; almost 90% of their speakers are located in just 10 of Mexico's 32 states, with Oaxaca having the highest number of speakers. The 10 states, in rank order, are Oaxaca, Vera Cruz, Chiapas, Yucatán, Puebla,

stress to an ever closer examination of the phonology/morphology interface, as this might be captured in a variety of OT models, then 'metrical phonology' has seemed to become an unfulfilled project – despite still having a great deal to say.

Mexico: Language Situation

M A French

This article is reproduced from the previous edition, volume 5, p. 2485, © 1994, Elsevier Ltd.

The national language of Mexico and the mother tongue of over 90% of its 84 million inhabitants (1989) is Spanish, making Mexico the largest Spanish-speaking country in the world. In addition, there are well over 50 indigenous minority ethnolinguistic groups, amounting to a total of over 6 million people. Many of these groups subsume more than one language.

Most of the surviving indigenous languages are in the eastern half of the country, mainly in rural areas; almost 90% of their speakers are located in just 10 of Mexico's 32 states, with Oaxaca having the highest number of speakers. The 10 states, in rank order, are Oaxaca, Vera Cruz, Chiapas, Yucatán, Puebla,

Estado de México, Hidalgo, Guerrero, Distrito Federal, and San Luis Potosí. The only state with a majority of indigenous language speakers is Yucatán, while in both Quintana Roo and Oaxaca over 40% speak minority languages. According to the 1980 census, the five largest minority languages were Nahuatl (also called Mexicano), with about 27% of the total of minority language speakers (aged 5 or over), Yucatec-Maya (13%), Zapotec (8%), Mixtec (6%), and Otomí (6%). However, of these five, only the second refers to a single, relatively homogeneous language; the others are, in reality, families of closely related languages (with a single general name). The expression '(linguistic) group' (e.g., 'Mixtec group') is a convenient cover term for such families and for so-called language complexes (linguistic and geographic continua in which only adjacent varieties are mutually intelligible).

Probably less than half of the indigenous languages spoken at the time of the Spanish conquest survive. The proportion of speakers of indigenous languages fell from 15% (1900 census) to only 3% in the censuses of 1950 and 1960. The 1970 census, however, showed an increase to over 6% while the 1980 figure was almost 8%. The 1980 census revealed that more than 75% of minority language speakers (aged 5 or over) could also speak Spanish. The majority of indigenous language-speaking communities exhibit unstable bilingualism, with various rates of shift to Spanish. Most indigenous languages show extensive borrowing from Spanish.

Many of the languages once spoken in the north have disappeared. Indeed, with one small exception, the north-east part of Mexico is now entirely Spanish speaking. In the northwest, the main indigenous languages all belong to the Uto-Aztecan language family; the largest of these are the Tarahumara group, mainly in Chihuahua, with about 60 000 speakers, and Mayo, on both sides of the Sonora/Sinaloa border, with about 50 000 speakers.

Mexico City is on the site of the capital of the empire of the Aztecs. Nahuatl, their language, was the official language of the empire and was later spread further through its use for a time as a lingua franca under the Spanish. Nahuatl-speaking areas are still to be found in various parts of central Mexico; the Nahuatl group (in many varieties, some called Nahuat and Nahual) has more than 1 250 000 speakers; the variety with the most speakers is Huasteca Nahuat (700 000) in San Luis Potosí and Hidalgo, with two main dialects, but Nahuatl speakers are also numerous in the states of Puebla (over 200 000 speakers), Vera Cruz (over 100 000), and Morelos and Guerrero (about 80 000 each).

Most of the other languages of central Mexico and Oaxaca belong to the Otomanguean (OM) superfamily. In the northwest of the area are Tarascan (Purépecha), a language isolate (spoken by about 100 000 people) in central Michoacán; the Otomí group (OM, with about 300 000) mainly in Hidalgo; and Mazahua (OM, with about 200 000) mainly in Estado de México. In the northeast of the central area the principal indigenous languages are Huasteca Nahuat and Sierra de Puebla Nahuat (125 000) in northeastern Puebla; Huastec (100 000), the most westerly language of the Mayan family, in eastern San Luis Potosí and northern Vera Cruz; and the Totonac group (200 000) in northern Puebla and adjacent parts of Vera Cruz. To the south, in addition to Nahuatl (in Morelos and northern Guerrero), there is the Mixtec group (OM, with about 300 000 speakers) mostly in western Oaxaca but also in eastern Guerrero. Also located in eastern Guerrero is Tlapanec (OM), with about 50 000 speakers. The Mazatec group (OM), in the extreme north of Oaxaca, has over 100 000 speakers, while the Zapotec group (OM) is spoken in central and eastern Oaxaca by around 500 000 people. The Mixe group, mainly in northeastern Oaxaca, has, in total, some 50 000 speakers.

The other main indigenous languages of Mexico all belong to the Mayan language family, which extends into much of Guatemala and parts of Belize. In central Chiapas are found the closely related Mayan languages Tzeltal (200 000 speakers) and Tzotzil (100 000). The Mayan language with the largest number of speakers (about 665 000) is Yucatec (or Yucatec-Maya), situated in the Yucatán peninsula (Campeche, Quintana Roo, Yucatán), with the great majority of speakers in the last-named state. Yucatec is the largest and most flourishing language of Mexico after Spanish. Although most of its speakers also know Spanish, language shift is slight.

Practically all broadcast and published material in Mexico is in Spanish. Spanish is also the medium at all levels of education. Literacy in indigenous languages is rare.

Meyer, Kuno Edward (1858–1919)

G Mac Eoin, National University of Ireland, Galway, Ireland

© 2006 Elsevier Ltd. All rights reserved.

Kuno Meyer was born in Hamburg on the 20th of December 1858 as the younger brother of Edouard Meyer, the great German historian. He spent some of his teenage years in Scotland, where he heard Gaelic spoken. This inspired him to study Celtic under Ernst Windisch at Leipzig University. He took his doctorate in 1884 with an edition of the medieval Irish story of Philipp and Alexander, the earliest of the translations from Latin to Irish. In 1885, he published an edition of *Cath Finntrága* (The Battle of Ventry), an early modern tale of the Fianna. In the same year, he was appointed lecturer in the Teutonic languages at the University of Liverpool. This, with promotion to Professor in 1895, was his post for 27 years. He developed arthritis in his thirties through spending nights on the Welsh hills with John Sampson, the Librarian of Liverpool University and the great authority on the language of the gypsies. Meyer's interest was in Celtic rather than in Teutonic. In 1896 he founded the *Zeitschrift für celtische Philologie*, which is happily still with us. In 1903, with the cooperation of John Strachan, he founded the School of Irish Learning in Dublin, aimed at the cultivation of Irish scholarship among the Irish and the provision of scholarships to enable Irish students to study on the continent. This has been the principal source of Irish scholars and scholarship in the century or so since its foundation. In 1912, on the death of Heinrich Zimmer, he was appointed Professor of Celtic at the University of Berlin. On leaving his post in Liverpool, his friends presented him with a festschrift entitled *A Miscellany presented to Kuno Meyer* (1912). In that year the freedom of the cities of Dublin and Cork was conferred on him.

On the outbreak of World War I, Meyer's patriotic sympathies with Germany came to the fore. He was appointed envoy to the United States with the task of contacting the American-Irish organizations and persuading them to influence the American government to refrain from entering the war on the side of the British and French. This he did with vigor, to the disappointment of his British friends. In particular his dating of a contribution to the *Zeitschrift für celtische Philologie* in 1914 with *Am Tage der Eroberung von Antwerpen* (on the day of the capture of Antwerp) incensed them. His name was struck off the list of freemen of Dublin and Cork and many of his friends severed all contact with him. In 1915, he was injured in a railway accident and was tended by a nurse, Mrs Florence Lewis, whom he married on December 10, 1915. The marriage was not happy and, having been facilitated in his return to Germany by the U.S. government, they parted. A short time thereafter Meyer became ill and died on October 11, 1919. Although he had been trained as a linguist, Meyer's interest was in literature, and he aroused the interest of the general public in the literature of Old Irish by his translations into perfect English. He also worked in etymology and in metrics. He edited a great number of Old and Middle Irish texts. A full bibliography of his publications was published by R. I. Best.

He studied at the Universities of Zürich, Berlin, and Paris and held chairs of Romance philology at the Universities of Jena (where he was appointed in 1887), Vienna (1890–1915), and Bonn. Trained in the positivist Neogrammarian school, he remained faithful to it throughout his life. However, even those adherents of idealist, sociolinguistic, generativist, or other anti-Neogrammarian schools who would find themselves

profoundly out of sympathy with Meyer-Lübke's firmly held doctrinal standpoint, would be unlikely to deny him his place as one of the most influential figures in the whole history of Romance linguistics, much of whose work remains of considerable value. He established his reputation at a remarkably young age (witness his appointment to the Jena chair when he was only 26) and as early as 1888 contributed the section on 'Die lateinische Sprache in den romanischen Ländern' to Gustav Gröber's *Grundriss der romanischen Philologie*. Before he was 30, the first volume of his own monumental (and still usable) grammar of the Romance languages had appeared. His other principal publication is his Romance etymological dictionary (1914–1920), which went through three editions in his lifetime and was reprinted as recently as 1968. He also published, *inter alia*, a historical grammar of French and studies of the Old Logudorese dialect of Sardinian and of Catalan. He died in Bonn on October 4, 1936.

Michif

P Bakker, Aarhus University, Aarhus, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Michif (/mitšif/; Mitchif, Mitif, erroneously also spelled Métchif) is a mixed language spoken by some of the Métis in Canada and the United States. The Métis are a separate ethnic group, who came into being as a result of European men marrying Amerindian women. Around the year 2000, the number of speakers had dwindled to fewer than 1000, in scattered locations mostly in Saskatchewan, Manitoba (Canada), North Dakota, and Montana (United States). All speakers are elderly. The language is highly endangered.

Mixed European-Amerindian marital unions took place from the first days of contact in New France. In the early period, the children of these relationships were typically raised by the mother as aboriginal children. In the early 1800s, the children of mixed parentage increasingly identified as separate from Europeans and from Amerindians, which was strengthened by political developments such as free trade, in which many such people were involved (Dickason, 1985). They called themselves *La Nouvelle Nation*, and also Mitif, Métis, Halfbreed, and similar terms. The name of the language is regularly derived from the term Mitif, which was the name for a person of mixed parentage in New France in the early 1600s.

The Métis combine aspects of Native cultures and French Canadian culture. Traditionally, the Métis had a very diverse lifestyle throughout the 19th century. Many were farmers, hunters, traders, and/or craftsmen. The hunters were especially famous for their massive buffalo hunts, until the near extinction of this animal in the late 1800s. Linguistically, the Métis were and are diverse as well, counting speakers of Ojibwe, Cree (both Algonquian), French, English (mostly in recognizable ethnic variants) as well as Michif, which combines, roughly, Cree verbs with French nouns. This is a typical example, from a fairy tale told by Norman Fleury in January 2004 (French elements in bold):

(1) **sa** **fam,** **sa** **pramyer**
3-POSS *woman* *3-POSS* *first-F*
fam kii-wanih-eew
woman *PST-lose.AN-3.SUBJ.3OBJ*

Michif (/mitšif/; Mitchif, Mitif, erroneously also spelled Métchif) is a mixed language spoken by some of the Métis in Canada and the United States. The Métis are a separate ethnic group, who came into being as a result of European men marrying Amerindian women. Around the year 2000, the number of speakers had dwindled to fewer than 1000, in scattered locations mostly in Saskatchewan, Manitoba (Canada), North Dakota, and Montana (United States). All speakers are elderly. The language is highly endangered.

Mixed European-Amerindian marital unions took place from the first days of contact in New France. In the early period, the children of these relationships were typically raised by the mother as aboriginal children. In the early 1800s, the children of mixed parentage increasingly identified as separate from Europeans and from Amerindians, which was strengthened by political developments such as free trade, in which many such people were involved (Dickason, 1985). They called themselves *La Nouvelle Nation*, and also Mitif, Métis, Halfbreed, and similar terms. The name of the language is regularly derived from the term Mitif, which was the name for a person of mixed parentage in New France in the early 1600s.

The Métis combine aspects of Native cultures and French Canadian culture. Traditionally, the Métis had a very diverse lifestyle throughout the 19th century. Many were farmers, hunters, traders, and/or craftsmen. The hunters were especially famous for their massive buffalo hunts, until the near extinction of this animal in the late 1800s. Linguistically, the Métis were and are diverse as well, counting speakers of Ojibwe, Cree (both Algonquian), French, English (mostly in recognizable ethnic variants) as well as Michif, which combines, roughly, Cree verbs with French nouns. This is a typical example, from a fairy tale told by Norman Fleury in January 2004 (French elements in bold):

(1) **sa** **fam,** **sa** **pramyer**
3-POSS *woman* *3-POSS* *first-F*
fam kii-wanih-eew
woman *PST-lose.AN-3.SUBJ.3OBJ*
'He had lost his wife, his first wife.'

(2) eekwa kiihtwam kii-wiiw-eew
then *again* *PST-marry-3.SUBJ.3OBJ*
'And now he had remarried.'

(3) kii-wiikim-eew onhin **la** **fam**-a
PST-marry-3.SUBJ.3OBJ *this-OBV* *the* *woman-OBV*
'He had married this woman.'

(4) **sitenn** **moves** **fam,** **enn** **moves** **fam**
it.was.F *bad-F* *woman* *a-F* *bad* *woman*
'She was a bad woman. A bad woman.'

(5) kii-machi-manitu-wi-w awa **la** **fam**
PST-bad.spirit-BE-3SG *this-AN* *the-F* *woman*
'She was a real devil, this woman.'

(6) **pi** **ilave** **trwaa** **fiy** ana
and *she-had* *three* *girl* *this-AN.SG*
kii-ayaw-eew **la** **fam**
PST-have-3SG *the-F* *woman*
'And she had three daughters, this woman had.'

This fragment, using a unified orthography for the two components, illustrates some aspects of the mixture of the language. In this fragments all verbs are from Cree, except the two copulas *sitenn* (F. *c'est une*) and *ilave* (F. *il/elle avait*). The nouns are all from French, including definite and indefinite articles and possessives (*la, lii, aen, enn*), the demonstratives from Cree (*awa, ana, onhin*), numerals from French (*trwaa, pramyer*), and conjunctions and adverbs from Cree (*kiihtwam, eekwa*) or French (*pi* < F. *puis*).

Sentential word order is free: (1) shows Object-Verb word order, (3) Verb-Object. Some preverbal modifiers can be separated from their nouns, notably numerals from the nouns, and in (6) a demonstrative from the noun. In morphology, French elements display French derivational and inflectional elements, whereas Cree elements combine with Cree morphology. The Cree noun *mushum* 'grandfather' gets Cree possessives and plural morphemes (*ni-mushum-ak* 1SG-grandfather-PL 'my grandfathers'). There are a few exceptions, such as the nontopic or so-called obviative suffix as in *la fam-a* in (3) that is often added to French nouns, and borrowed or code-switched French and English verbs as in *gii-li-park-ii-naann* 1PST-MARKER-park-INF-1PL 'we parked' or *kii-li-move-ii-w* PST-MARKER-move-INF-3SG 'she moved (away)'. This sentence switches languages four times: Cree-French-English-French-Cree.

The phoneme inventory of Michif is a combination of the inventories of the Métis variety of French (influenced by a Northern dialect of Cree) and Southeastern Plains Cree (influenced by Saulteaux Ojibwe). For instance, preaspirated consonants and nasal /i/ are only found in words of Cree etymology, and phonemes such as /r/ and /l/ are only found in the French part. Strikingly, the range of allophones for Cree and French phonemes differs: whereas voiced /b/ and unvoiced /p/ (and other stops and fricatives) are allophones in Cree between vowels, they are distinct phonemes in the French part. The Cree and French components also follow their own phonotactic patterns. Only stress patterns seem to have moved in the direction of Cree.

Michif combines Cree and French agreement: the (Algonquian) animacy of nouns is reflected in the gender inflection of demonstratives and verbs, and the (French) masculine-feminine distinction is shown in definite and indefinite articles and preverbal adjectives.

Michif is more complex than both of its components, having two parallel semantic, phonological, morphological, and syntactic systems. It combines the complexity of the Algonquian verb, with hundreds of forms, with the irregularities of French nominal derivation.

The language probably came into being in the early 19th century, parallel with the development of a new identity of mixed persons as a new ethnic group. Michif is associated with descendants of the Métis buffalo hunters and their winter camps, and it is likely that these hunts played a role in the dissemination of the language.

Michif belongs to the small set of mixed or intertwined languages, of which a few dozen examples are known from all parts of the world. Whereas other such languages usually combine the grammatical system of one language with the lexicon of another, Michif seems to be almost unique in that it combines verbs from one language with nouns from another. Only the Nigerian language Igbo-Okrika seems to display a similar pattern (Igbo verbs, Ijo nouns).

The Federated States of Micronesia (FSM) is a linguistically diverse Pacific nation consisting of numerous high volcanic islands and low coral atolls. Estimates of the number of speakers of the 15 indigenous languages spoken within the four states of FSM (based on 1980 census data) are provided here in parentheses after each language name.

Kosrae State, the easternmost state of FSM, contains only the single high island of Kosrae. The language of this island is Kosraean (4700), formerly Kusaiean.

Pohnpei State takes its name from the high island of Pohnpei (formerly Ponape), the site of the FSM capital. Pohnpeian (19 700), also known as Ponapean, is the principal language of its inhabitants. A dialect of Pohnpeian and an English/Pohnpeian-based creole are spoken on the nearby atoll of Ngatik. Mokilese (1050) and Pingelapese (1300), which border on mutual intelligibility with Pohnpeian, and Nukuoro (550) and Kapingamarangi (1300), Polynesian outliers, are spoken on neighboring atolls. Speakers of these atoll languages, as well as speakers of Mortlockese from Chuuk State, have established colonies on Pohnpei and maintain use of their languages.

All the languages of Chuuk State are members of the Chuukic continuum. Degrees of mutual intelligibility among the many dialects that make up this continuum decline as one moves across the chains of islands making up this state. The exact number of languages in this continuum is consequently indeterminate, but five language names are commonly cited. Chuukese (31 500), formerly Trukese, is spoken on the high and reef islands of the Chuuk Lagoon. Mortlockese (11 000), Pááfang (1300, in the Hall Islands) Namonuito (750), and Puluwatese (1500, on Puluwat, Pulap, and Pulusuk) are spoken on atolls within this state. Colonies of speakers of these atoll languages also reside on the island of Moen in the Chuuk Lagoon.

The Chuukic continuum continues into Yap State. Ulithian (1100), Woleaian (1900), and Satawalese (500), all Chuukic languages, are spoken on atolls to the east of the high island of Yap. On Yap, the indigenous language is Yapese (5800). Yapese is only distantly related to the other languages of Micronesia.

Kosraean, Pohnpeian, Chuukese, and Yapese, all high-island languages, serve as official languages for the states with corresponding names. English is a second official language in all states. Ulithian has semiofficial status as a language representing the Chuukic-speaking atolls of Yap. Official languages are employed in the media and serve as lingua francas within each state. English is an official language and lingua franca of the nation.

English is promoted through transitional programs of bilingual education. Children are educated in their native language in the first few years, with an increasing emphasis on English throughout the first eight years of schooling. Secondary and tertiary instruction are almost exclusively in English. Use of the indigenous languages remains robust, but English is encroaching into all realms of discourse.

Microparametric Variation

A Henry, University of Ulster, Antrim, UK

© 2006 Elsevier Ltd. All rights reserved.

What Is Syntactic Variation?

Syntactic variation exists on larger and smaller scales. On a large scale, languages clearly differ from one another in many ways; such variation is captured within Chomskyan theoretical syntax with reference to parameter setting. However, 'syntactic variation' generally means the finer-grained variation within a speech community or within the grammars of individual speakers. Such variation is sometimes referred to as 'microparametric variation' or microvariation within theoretical linguistics.

For example in English, we find variation across dialects and in the grammars of individual speakers in relation to such aspects as subject-verb agreement,

as in (1) and (2) below, negative concord as in (3) and (4), and the use of relative pronouns in relative clauses, as in (5) and (6).

(1) There are students at the door.

(2) There's students at the door.

In sentences like (1) and (2), some speakers have obligatory agreement of the verb with the post-verbal noun phrase, so that only (1) is grammatical. Others always use sentences like (2), where the verb does not agree with the post-verbal noun phrase, so that only (2) is grammatical. For many speakers, however, both are grammatical, with (1) used more in formal settings and (2) in more informal settings.

(3) I didn't see nobody.

(4) I saw nobody.

Many speakers of English allow sentences like (3), with negative concord (so that the sentence means the same as (4), whereas some only allow sentences like (4), without negative concord.

(5) It's always you who makes the decisions.

(6) It's always you makes the decisions.

Again, some speakers allow sentences like (6), as well as (5).

To take an example from another language, in French we find variability in the use of inversion in questions and of *ne* in negatives:

(7) Il lit beaucoup de livres?
He reads many of books
'Does he read many books'?

(8) Lit-il beaucoup de livres?
Reads-he many of books
'Does he read many books'?

(9) Elle ne va pas a Paris
She neg-particle goes not to Paris
'She is not going to Paris'.

(10) Elle va pas a Paris
she goes not to Paris
'She is not going to Paris'.

The following examples from Classical Arabic also show optional variation in word order (Wright, 1896:100)

(11) كَانَ قائِماً زَيْدٌ
Kâna zaydun qâ'iman
Was(3sg) Zeid(nom) standing (acc)
'Zeid was standing'.

(12) زَيْدٌ قائِماً كَانَ
Kâna qâ'iman zaydun
Was(3sg) standing Zeid
'Zeid was standing'.

These examples are taken from only three languages, but examples can, of course, be found in a wide range of languages.

Approaches to Variation in Syntax

There are two major approaches to studying syntactic variation. One, from sociolinguistics, essentially studies language at the level of the speech community, focusing on the ways in which groups of speakers vary in their use of syntax and how this variation relates to nonlinguistic variables, such as social class, gender, age, and the degree of formality of the interaction. At an early stage in his pioneering work on language variation, Labov (1969) studied variation in the use of the copula in African-American English. Key figures in the study of variation in syntax from the sociolinguistic perspective have been Cheshire (1982) and Tagliamonte (1998). Such study is typically based on the collection of a corpus of recorded data from a range of speakers. It generally aims to study language at the community rather than individual level.

Variation is also studied within syntactic theory. Although much of syntactic theory has been concerned with establishing what is common to all languages (Universal Grammar) and how languages differ from one another, a body of work now exists on what is usually termed microparametric variation or microvariation; that is, differences between closely related dialects (see, for example, Haegeman, 1992; Henry, 1995; Black and Motapanyane, 1996). This is a relatively recent development within this framework, and there have as yet been very few studies of nonstandard varieties of English, for example. One reason for this may be that theoretical linguists typically work on their own intuitions and those of their colleagues and students, and these groups both tend to be relatively standard speakers, at least on reaching higher education. In general, work in syntactic theory relies on the intuitions of native speakers as data, rather than on the recording of actual speech. This reliance may reduce the amount of variation observed, because if native speakers are only asked about one form of a structure, the linguist may not realize that there is another possible form. For example, the linguist studying agreement in sentences with expletive *there* may only seek to establish whether the verb can agree with the associate, as in:

(12) There were three books on the table.

and omit to test whether there is an alternative form such as (13):

(13) There was three books on the table.

Recent work developing optimality theory, an alternative approach to grammar that was originally developed in relation to phonology as an approach to syntax, has offered a possible alternative view of syntactic variation as arising from different rankings of violable constraints. Work on syntactic variation in this framework has not as yet been highly developed, however.

Indeed, studies of syntactic variation within theoretical linguistics, as well as within sociolinguistics and theoretical linguistics, have been comparatively sparse. Within sociolinguistics, studies of syntactic variation have been greatly outnumbered by studies of phonological variation. No doubt, one reason for this is that phonological variables occur much more frequently than do syntactic variables in recorded data. Thus, if one is interested in whether or not /r/ is pronounced, it is likely that even a relatively short stretch of recording will produce many instances of the variable. However, if one is interested, for example, in variation in the structure of passive sentences, then these types of sentences are going to occur relatively infrequently in data. For example, the Belfast database available on CHILDES, the child language database, contains 130 hours of recording, much of it in fact adult-adult conversations. However, if one looks in it for individual variables, the number of examples are actually rather sparse: for example, there were only three examples of the structure, 'I'm only after Verb-ing', (meaning 'I just Verbed'), which most speakers of the variety find grammatical. Thus, studies of syntactic variation within sociolinguistics have not only been rather few in number, but have typically focused on frequently occurring elements; for example, forms of the verb *be*.

A further problem is establishing that alternative forms of syntax in fact have the same meaning. A 'sociolinguistic variable' is an alternative way of saying the same thing, but it is much easier to identify such alternatives in phonology than in syntax. Thus, for example as noted above, many colloquial varieties of English have negative concord, where two negative elements occur in the sentence with only a single negative interpretation:

(14) I didn't say nothing.

(15) They don't know nobody.

As alternatives to these, speakers use forms without negative concord, for example:

(16) I said nothing.

(17) I knew nobody.

However, in order to consider this alternation as an example of a sociolinguistic variable, we would need to be able to show that these alternative forms of syntax mean exactly the same, and that is not absolutely clear – some speakers of negative concord varieties feel that the examples with negative concord are more emphatically negative.

It is particularly important to note that variation from standard language syntax is not deviation from the standard form, but rather an equally linguistically valid means of expressing the same sentence. Thus, to say (14) and (15) above is not to deviate from the rule of standard English that allows only one negative per clause, but rather to follow a different rule; that negative concord varieties are just as rule-governed as standard varieties is shown, for example, by the fact that, in most English negative concord dialects, it is ungrammatical to have an N-word, such as *nothing* or *nobody,* precede the verbal negative marker *not* or its contracted form *n't*. Thus, sentences like the following are ungrammatical, unless they are given a double-negative reading, in many negative concord varieties of English.

(18) Nobody didn't help.

(19) Nothing wouldn't surprise me.

Within syntax, the question of whether there is variation within individual grammars has never been resolved fully. At an early stage in the development of generative syntax, Chomsky (1965) posited that the goal of study should be the linguistic competence of the "ideal speaker-hearer in a homogeneous speech community." This is clearly an idealization, and Chomsky was not claiming that such communities existed, but rather that it is a legitimate idealization to study language *as if* this were the case; some would argue, however, that, in doing so, one of the essential characteristics – its variability – is excluded, thus distorting the understanding of how human language works. Some models of syntactic theory in fact hold that there is 'no optionality' (see, for example, Chomsky, 1995, 2000, 2001a, 2001b) and that where speakers apparently have two or more options within a grammar, they must in fact have two separate grammars, being in effect bidialectal. A considerable amount of effort has gone into showing that apparently variable features are not really variable or that such variation is very highly constrained.

However, not all syntacticians agree that variation involves switching between separate grammars. For example, Henry (1995), in a study of syntactic variation in Belfast English, argued that the type of variation found between dialects is of exactly the same type as that found between languages and that it involves the settings of parameters; however, this work suggested that different settings

of the same parameter can be present in individual grammars.

Some studies have sought to reconcile the sociolinguistic and syntactic theory approaches; for example, see Wilson and Henry (1998), who argued for an integration of the findings of generative syntax into sociolinguistics, and Corrigan and Cornips (2005), a collection of papers in which sociolinguists and syntacticians search for an integrated approach to variation. One of the reasons it is difficult to find a common approach is that, although the area of study of syntactic theory is the representation of syntax in the mind/brain, sociolinguistic theory is studying the relationship of language to society and thus gathers data in general at a group rather than individual level.

The study of variation has also been important in the study of syntactic change. Kroch (for example, 1989) has studied variation in historical texts in English, for instance, between the use of DO-support and verb movement (i.e., alternations, such as 'Do you have any change?' versus 'Have you any change?'). He proposed that variation is caused by competing grammars coexisting in the community or the individual. This offers an explanation for why language change often takes place not dramatically, as one might expect from a pure parameter setting model, but very often with old and new forms being used side by side over a considerable period of time.

Syntactic variation is also a noticeable feature of first language acquisition. Thus, when children first develop a new syntactic structure – for example, the use of inversion in English questions – they use it optionally, alternating for a period between questions without inversion (their previous grammar) and questions with inversion (their new grammar).

(20) You can play?

(21) Can you play?

This variation seems to be a natural feature of language acquisition, applying to many aspects, including the acquisition of both grammatical morphemes and syntactic structures. In general, children's developing grammars, although not adult-like, conform to the requirements of Universal Grammar; therefore, the fact that they contain so much variability may indicate that syntactic variation is the norm, rather than the exception, in human language grammars.

Though there were occasional bilingual glossaries and word lists written in the Middle English period itself (c. 1100–c. 1500), it was not until the second half of the 19th century that comprehensive dictionaries of Middle English began to be written. The first, by Herbert Coleridge, editor of the fledgling *Oxford English dictionary* (*OED*), appeared in 1859, but it was limited to early Middle English (1250–1300) and intended primarily as a 'foundation-stone' for the larger dictionary; it contains brief glosses for some words, occasional etymologies or notices of cognates, and references to illustrative examples, but no quotations. The next, by the German F. H. Stratmann, was published in 1867 (having been written in parts between 1864 and 1867) and then appeared in further editions until the end of his life in 1884; it is based on nearly 200 editions of texts, with brief glosses in English and/or Latin for most words, notices of variant spellings and grammatical forms, etymologies and notices of cognates, and either references to illustrative examples or a selection of (usually brief) quotations. In 1878 another German, Eduard Mätzner, began to publish his *Wörterbuch,* beginning with the letters A–D; this dictionary was planned on a larger scale than any of the other 19th-century dictionaries, with full sets of definitions (often subdivided), lists of variant spellings, brief etymologies, and extended illustrative quotations, but it only reached the middle of the letter M (even so, it amounted to some 1880 pages, compared to some 750 for Stratmann's latest edition). A. L. Mayhew and W. W. Skeat's (1888) was next: it is based on the glossaries to only 11 published collections of texts, but useful for the student; it has brief but adequate glosses, lists of variant spellings and (frequently) etymologies, and references to illustrative examples but no quotations. A few years later, in 1891, Henry Bradley, the second editor of the *OED,* published a revision, rearrangement, and enlargement of Stratmann, running to a little over 700 pages and based on nearly 300 editions; the main differences are its formal (rather than etymological) arrangement of words, stricter alphabetization, and the addition of more words of Romance origin. Like Stratmann, it contains brief glosses (though more precise and in English only), etymologies and notices of cognates, notices of spellings and forms, and either references to illustrative examples or a selection of (usually brief) quotations.

In 1919, as the *OED* was nearing completion, W. A. Craigie, the third editor, proposed a series of period dictionaries of English to extend and supplement the treatment in the *OED,* one of which was a dictionary of Middle English on historical principles. Work began on it at Cornell University in 1925, and in 1930, now called the *Middle English dictionary* (*MED*), it moved to the University of Michigan. The *MED* is based on a collection of quotations from Middle English texts written in England, Ireland, and Wales, having as its nucleus those that had been extracted for the *OED* (c. 430 000) and the additional ones extracted at Cornell (c. 175 000); the collection has since grown to some 3 000 000 slips. Between 1930 and 1945, under editors Samuel Moore and then Thomas Knott, a reading program to supplement the original collection of quotations was carried out, a dialect survey completed, and experiments with editorial plans and some preliminary editing performed. In 1946–1947 newly appointed editor Hans Kurath drew up a formal editorial plan, editing began in a systematic way, and in 1952 the first fascicle was published. Work progressed slowly but deliberately, and the last fascicle (of 115) appeared in 2001; there is now an electronic version of the *MED,* as part of the online *Middle English compendium.*

The completed *MED,* which runs to nearly 15 000 pages, over 55 000 separate entries, and nearly 900 000 quotations, contains brief definitions, preferably Modern English equivalents if available, with the definitions becoming more detailed and more precise as the work progresses; a full and systematic treatment of spellings, grammatical forms, and regional variants; etymologies containing the immediate source of the word, with variants noted if they are reflected in the Middle English spellings; and a full

Between 1930 and 1945, under editors Samuel Moore and then Thomas Knott, a reading program to supplement the original collection of quotations was carried out, a dialect survey completed, and experiments with editorial plans and some preliminary editing performed. In 1946–1947 newly appointed editor Hans Kurath drew up a formal editorial plan, editing began in a systematic way, and in 1952 the first fascicle was published. Work progressed slowly but deliberately, and the last fascicle (of 115) appeared in 2001; there is now an electronic version of the *MED,* as part of the online *Middle English compendium.*

The completed *MED,* which runs to nearly 15 000 pages, over 55 000 separate entries, and nearly 900 000 quotations, contains brief definitions, preferably Modern English equivalents if available, with the definitions becoming more detailed and more precise as the work progresses; a full and systematic treatment of spellings, grammatical forms, and regional variants; etymologies containing the immediate source of the word, with variants noted if they are reflected in the Middle English spellings; and a full

display of illustrative quotations for each sense, chronologically arranged, with at least one quotation for each quarter-century, if available. Special features are the 'double-dating' system (all texts are given manuscript dates, with composition dates added in parentheses for texts composed a quarter of a century or more earlier) and the use of surnames and place names (primarily to corroborate etymologies by showing chronological links to the various source languages).
